## Table F. 1 - Recommended limiting values for composition and properties of concrete

|  | Exposure classes |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | No risk of <br> corrosion or <br> attack <br> X0 | Carbonation-induced corrosion |  |  |  | Chloride-induced corrosion |  |  |  |  |  | Freeze/thaw attack |  |  |  | Aggressive chemical environments |  |  |
|  |  |  |  |  |  | Sea water |  |  | Chloride other than from sea water |  |  |  |  |  |  |  |  |  |
|  |  | XC 1 | XC 2 | XC 3 | XC 4 | XS 1 | XS 2 | XS 3 | XD 1 | XD 2 | XD 3 | XF 1 | XF 2 | XF 3 | XF 4 | XA 1 | XA 2 | XA 3 |
| $\begin{aligned} & \hline \text { Maximum } \\ & \mathrm{w} / \mathrm{c} \end{aligned}$ | - | 0,65 | 0,60 | 0,55 | 0,50 | 0,50 | 0,45 | 0,45 | 0,55 | 0,55 | 0,45 | 0,55 | 0,55 | 0,50 | 0,45 | 0,55 | 0,50 | 0,45 |
| Minimum strength class | C12/15 | C20/25 | C25/30 | C30/37 | C30/37 | C30/37 | C35/45 | C35/45 | C30/37 | C30/37 | C35/45 | C30/37 | C25/30 | C30/37 | C30/37 | C30/37 | C30/37 | C35/45 |
| Minimum cement content ( $\mathrm{kg} / \mathrm{m}^{3}$ ) | - | 260 | 280 | 280 | 300 | 300 | 320 | 340 | 300 | 300 | 320 | 300 | 300 | 320 | 340 | 300 | 320 | 360 |
| Minimum air content (\%) | - | - | - | - | - | - | - | - | - | - | - | - | 4, $0^{\text {a }}$ | 4, ${ }^{\text {a }}$ | 4, $0^{\text {a }}$ | - | - | - |
| Other <br> requirements |  |  |  |  |  |  |  |  |  |  |  | Aggreg <br> EN 126 <br> freeze/ | ate in ac 620 with thaw res | ccordanc <br> sufficient <br> sistance | ce with |  | Sulfate cemen | esisting |

${ }^{\text {a }}$ Where the concrete is not air entrained, the performance of concrete should be tested according to an appropriate test method in comparison with a concrete for which freeze/thaw resistance for the relevant exposure class is proven.
${ }^{b}$ When $\mathrm{SO}_{4}{ }^{2-}$ leads to exposure Classes XA2 and XA3, it is essential to use sulfate-resisting cement. Where cement is classified with respect to sulfate resistance, moderate or high sulfate-resisting cement should be used in exposure Class XA2 (and in exposure Class XA1 when applicable) and high sulfate-resisting cement should be used in exposure Class XA3.

### 2.0 INDICATIVE DESIGN WORKING LIFE

(Ref. Section 2.3: MS EN 1990: 2010)

Table 2.1: Indicative design working life

| Design working <br> life category | Indicative design <br> working life (years) | Examples |
| :---: | :---: | :--- |
| 1 | 10 | Temporary structures ${ }^{(1)}$ |
| 2 | 10 to 25 | Replaceable structural parts, e.g. gantry girders, bearings |
| 3 | 15 to 30 | Agricultural and similar structures |
| 4 | 50 | Building structures and other common structures |
| 5 | 100 | Monumental building structures, bridges, and other civil engineering <br> structures |
| $(1)$ | Structures or parts of structure that can be dismantled with a view to being re-used should not be <br> considered as temporary |  |

### 3.0 EFFECTIVE WIDTH OF FLANGES (ALL LIMIT STATES) <br> (Ref. Section 5.3.2: MS EN 1992-1-1: 2010)

The effective flanged width, $b_{\text {eff }}$ for a T-beam or L-beam may be derived as
$b_{e f f}=\sum b_{e f f, i}+b_{w} \leq b$
where

$$
b_{\text {eff, } \mathrm{i}}=0.2 b_{\mathrm{i}}+0.1 l_{o} \leq 0.2 l_{\mathrm{o}}
$$

and

$$
b_{\mathrm{eff}, \mathrm{i}} \leq b_{\mathrm{i}}
$$

$l_{0}$ is the distance between point of zero moment can be obtained from Figure 5.2. Other notations are given in Figure 5.3.

Figure 5.2: Definition of $l_{0}$ for calculation of effective flanged width

Figure 5.3: Effective flanged width parameters

### 4.0 DURABILITY, FIRE AND BOND REQUIREMENTS (Ref. Section 4: MS EN 1992-1-1: 2010)

## Exposure Class

Table 4.1: Exposure class related to environmental conditions in accordance with EN 206-1
(Ref. MS EN 1992-1-1: 2010)

| $\begin{gathered} \text { Class } \\ \text { designation } \end{gathered}$ | Description of the environment | Informative examples where exposure classes may occur |
| :---: | :---: | :---: |
| No risk of corrosion attack |  |  |
| XC0 | For concrete without reinforcement or embedded metal: all exposure except where there is freeze/thaw, abrasion or chemical attack <br> For concrete with reinforcement or embedded metal: very dry | Concrete inside buildings with very low air humidity |
| 2 Corrosion induced by carbonation |  |  |
| XC1 | Dry or permanently wet | Concrete inside building with low air humidity Concrete permanently submerged in water |
| XC2 | Wet, rarely dry | Concrete surfaces subject to long-term water contact Many foundations |
| XC3 | Moderate humidity | Concrete inside buildings with moderate or high air humidity <br> External concrete sheltered from rain |
| XC4 | Cyclic wet and dry | Concrete surfaces subject to water contact, not within the exposure class XC2 |
| 3 Corrosion induced by chlorides |  |  |
| XD1 | Moderate humidity | Concrete surfaces exposed to airborne chlorides |
| XD2 | Wet, rarely dry | Swimming pools <br> Concrete components exposed to industrial waters containing chlorides |
| XD3 | Cyclic wet and dry | Parts of bridges exposed to spray containing chlorides <br> Pavements <br> Car park slabs |
| 4 Corrosion induced by chlorides from sea water |  |  |
| XS1 | Exposed to airborne salt but not in direct contact to sea water | Structures near to or on the coast |
| XS2 | Permanently submerged | Parts of marine structures |
| XS3 | Tidal, splash and spray zones | Parts of marine structures |
| 5 Freeze/Thaw attack |  |  |
| XF1 | Moderate water saturation, without de-icing agent | Vertical concrete surfaces exposed to rain and freezing |
| XF2 | Moderate water saturation, with de-icing agent | Vertical concrete surfaces of road structures exposed to freezing and air-borne de-icing agents |
| XF3 | High water saturation, without de-icing agents | Horizontal concrete surfaces exposed to rain and freezing |
| XF4 | High water saturation, with de-icing agents or sea water | Road and bridge decks exposed to de-icing agents Concrete surfaces exposed to direct spray containing de-icing agents and freezing <br> Splash zone of marine structures exposed to freezing |
| 6 Chemical attack |  |  |
| XA1 | Slightly aggressive chemical environment according to EN 206-1, Table 2 | Natural soils and ground water |
| XA2 | Moderately aggressive chemical environment according to EN 206-1, Table 2 | Natural soils and ground water |
| XA3 | Highly aggressive chemical environment according to EN 206-1, Table 2 | Natural soils and ground water |

## Concrete Cover

The nominal cover is given as:
$c_{\text {nom }}=c_{\text {min }}+\Delta c_{\text {dev }}$
where $\quad \Delta c_{\mathrm{dev}}$ is an allowance which should be made in the design for deviation from the minimum cover. It should be taken as 10 mm . It is permitted to reduce to 5 mm if the fabrication subjected to a quality assurance system
$c_{\text {min }}$ is the minimum cover sets to satisfy the requirements for safe transmission of bond forces, durability and fire resistance

## Minimum Cover for Bond

Table 4.2: Minimum cover, $c_{\text {min, }}$ b requirements regard to bond (Ref. MS EN 1992-1-1: 2010)

| Bond Requirement |  |
| :---: | :---: |
| Arrangement of bars | Minimum cover, $c_{\text {min, }}$. ${ }^{*}$ |
| Separated | Diameter of bar |
| Bundled | Equivalent diameter $\emptyset_{n}=\emptyset \sqrt{n_{b}} \leq 55 \mathrm{~mm}$ <br> where $n_{\mathrm{b}}$ is the number of bars in the bundle, which is limited to $n_{\mathrm{b}} \leq 4$ for vertical bars in compression <br> $n_{\mathrm{b}} \leq 3$ for all other cases |

## Minimum Cover for Durability

Table 4.4N: Minimum cover, $c_{\text {min, dur }}$ requirements with regards to durability for reinforcement steel in accordance with EN 10080 (Ref. MS EN 1992-1-1: 2010)

| Structural <br> Class | Exposure Class according to Table 4.1 EC 2 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{X 0}$ | $\mathbf{X C 1}$ | $\mathbf{X C 2 / X C 3}$ | $\mathbf{X C 4}$ | XD1/XS1 | XD2/XS2 | XD3/XS3 |
| S1 | 10 | 10 | 10 | 15 | 20 | 25 | 30 |
| S2 | 10 | 10 | 15 | 20 | 25 | 30 | 35 |
| S3 | 10 | 10 | 20 | 25 | 30 | 35 | 40 |
| S4 | 10 | 15 | 25 | 30 | 35 | 40 | 45 |
| S5 | 15 | 20 | 30 | 35 | 40 | 45 | 50 |
| S6 | 20 | 25 | 35 | 40 | 45 | 50 | 55 |

Table 4.5N: Minimum cover, $c_{\text {min, dur }}$ requirements with regards to durability for prestressing steel (Ref. MS EN 1992-1-1: 2010)

| Structural <br> Class | Exposure Class according to Table 4.1 EC 2 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{X 0}$ | $\mathbf{X C 1}$ | $\mathbf{X C 2 / X C 3}$ | $\mathbf{X C 4}$ | XD1/XS1 | XD2/XS2 | XD3/XS3 |
| S1 | 10 | 15 | 20 | 25 | 30 | 35 | 40 |
| S2 | 10 | 15 | 25 | 30 | 35 | 40 | 45 |
| S3 | 10 | 20 | 30 | 35 | 40 | 45 | 50 |
| S4 | 10 | 25 | 35 | 40 | 45 | 50 | 55 |
| S5 | 15 | 30 | 40 | 45 | 50 | 55 | 60 |
| S6 | 20 | 35 | 45 | 50 | 55 | 60 | 65 |

The minimum cover values for reinforcement and prestressing tendons in normal weight concrete taking account of the exposure classes and the structural classes is given by $c_{\text {min,dur }}$.

Note: Structural classification and values of $c_{\text {min,dur }}$ for use in a Country may be found in its National Annex. The recommended Structural Class (design working life of 50 years) is $S 4$ for the indicative concrete strengths given in Annex $E$ and the recommended modifications to the structural class is given in Table $4.3 N$. The recommended minimum Structural Class is S1.

Table 4.3N: Recommended structural classification (Ref. MS EN 1992-1-1: 2010)

| Structural Class |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Criterion | Exposure Class according to Table 4.1 |  |  |  |  |  |  |
|  | X0 | XC1 | XC2/XC3 | XC4 | XD1 | XD2/XS1 | XD3/XS2/XS3 |
| Design Working Life of 100 years | Increase class by 2 | Increase class by 2 | Increase class by 2 | Increase class by 2 | Increase class by 2 | Increase class by 2 | Increase class by 2 |
| $\begin{aligned} & \text { Strength } \\ & \text { Class }{ }^{(1)(2)} \end{aligned}$ | $\begin{gathered} \geq \mathrm{C} 30 / 37 \\ \text { Reduce } \\ \text { class by } 1 \\ \hline \end{gathered}$ | $\begin{gathered} \geq \mathrm{C} 30 / 37 \\ \text { Reduce } \\ \text { class by } 1 \\ \hline \end{gathered}$ | $\geq$ C35/45 <br> Reduce <br> class by 1 | $\begin{gathered} \geq \mathrm{C} 40 / 50 \\ \text { Reduce } \\ \text { class by } 1 \end{gathered}$ | $\begin{gathered} \geq \mathrm{C} 40 / 50 \\ \text { Reduce } \\ \text { class by } 1 \end{gathered}$ | $\begin{gathered} \geq \mathrm{C} 40 / 50 \\ \text { Reduce } \\ \text { class by } 1 \end{gathered}$ | $\geq \mathrm{C} 45 / 55$ <br> Reduce class by 1 |
| Member with Slab Geometry (position of reinforcement not affected by construction process) | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 |
| Special <br> Quality <br> Control of the Concrete <br> Production Ensured | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 | Reduce class by 1 |

## Notes to Table 4.3N:

1. The strength class and $\mathrm{w} / \mathrm{c}$ ratio are considered to be related values. A special composition (type of cement, w/c value, fine fillers) with the intent to produce low permeability may be considered.
2. The limit may be reduced by one strength class if air entrainment of more than $4 \%$ is applied.

## Minimum Cover for Fire (Ref. MS EN 1992-1-2: 2004)

Rather than giving a minimum cover, the tubular method based on nominal axis distance is used. This is the distance from the centre of the main reinforcement bar to the top or bottom surface of the member. The designer should ensure that:
$a \geq c_{\text {nom }}+\emptyset_{\text {link }}+\frac{\emptyset_{\text {bar }}}{2}$
where the nominal axis distance, $a$ is illustrated in Figure 5.2. The permissible combinations of member dimension and axis distance are given in Table 5.5 and 5.6 for beams and Table 5.8 for slabs.

Figure 5.2: Section through structural members, showing nominal axis distance $a$

Table 5.5: Minimum dimensions and axis distances for simply supported beams made with reinforced and prestressed concrete (Ref. Table 5.5 EN 1992-1-2)

| Standard Fire Resistance |  | Minimum Dimensions (mm) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Possible combinations of $a$ and $b_{\text {min }}$ where $a$ is the average axis distance and $b_{\text {min }}$ in the width of beam (mm) |  |  |  | Web thickness, $b_{\text {w }}$ (mm) |  |  |

### 5.0 EFFECTIVE SPAN OF BEAMS AND SLABS IN BUILDING <br> (Ref. Section 5.3.2.2: MS EN 1992-1-1: 2010)

The effective span of a member, $l_{\text {eff }}$ should be calculated as follows:
$l_{\text {eff }}=l_{\mathrm{n}}+a_{1}+a_{2}$
where $l_{\mathrm{n}}$ is the clear distance between the faces of the support
$a_{1}$ and $a_{2}$ is the $\min \{0,5 h ; 0.5 t\}$, where $h$ is the overall depth of the member and $t$ is the width of the supporting element

Figure 5.4: Effective span, $l_{\text {eff }}$ for different support conditions

### 6.0 DESIGN FOR FLEXURE

(Ref. Section 6.1: MS EN 1992-1-1: 2010)

## Design Procedure for Rectangular Section

Supposed the bending moment is $M$, beam section is $b \times b$, concrete strength is $f_{\text {ck }}$ and steel strength is $f_{\mathrm{yk}}$, to determine the area of reinforcement, proceed as follows:

The steps are only for valid for $f_{\text {ck }} \leq 50 \mathrm{MPa}$. For concrete compressive strength, $50 \mathrm{MPa}<f_{\text {ck }} \leq 90 \mathrm{MPa}$, modification of the stress block should be in accordance to Section. 3.1.7: MS EN 1992-1-1: 2010.

1. Calculate $K=\frac{M}{f_{c k} b d^{2}}$
2. Calculate $K_{\text {bal }}=0.363(\delta-0.44)-0.116(\delta-0.44)^{2}$
where $\delta=\frac{\text { Moment at section after redistribution }}{\text { Moment at section before redistribution }} \leq 1.0$
and for $\delta=1.0 \quad \rightarrow \quad K_{\text {bal }}=0.167$
3. If $K \leq K_{\text {bal }}$, compression reinforcement is not required, and
$z=d\left[0.5+\sqrt{\left(0.25-\frac{K}{1.134}\right)}\right]$
Calculate tension reinforcement:
$A_{s}=\frac{M}{0.87 f_{y k} Z}$
4. If $K>K_{\text {bal }}$, compression reinforcement is required, and
$z=d\left[0.5+\sqrt{\left(0.25-\frac{K_{b a l}}{1.134}\right)}\right]$
$x=\frac{(d-z)}{0.4}$
Calculate compression reinforcement:
Check d'/x:
$A_{S}^{\prime}=\frac{\left(K-K_{b a l}\right) f_{c k} b d^{2}}{0.87 f_{y k}\left(d-d^{\prime}\right)}$
if $d^{\prime} / x \leq 0.38$ or
$A_{s}^{\prime}=\frac{\left(K-K_{b a l}\right) f_{c k} b d^{2}}{f_{s c}\left(d-d^{\prime}\right)} \quad$ if $d^{\prime} / x>0.38 \quad$ where $\quad f_{\mathrm{sc}}=700\left(1-d^{\prime} / x\right)$
Calculate tension reinforcement:
$A_{s}=\frac{K_{b a l} f_{c k} b d^{2}}{0.87 f_{y k} z}+A_{s}{ }^{\prime}\left(\frac{f_{s c}}{0.87 f_{y k}}\right)$

## Design Procedure for Flanged Section

Supposed the bending moment is $M$, beam section is $b_{\mathrm{w}} \times b \times d \times h_{\mathrm{f}}$, concrete strength is $f_{\mathrm{ck}}$ and steel strength is $f_{\mathrm{yk}}$, to determine the area of reinforcement, proceed as follows:

1. Calculate $M_{f}=0.567 f_{c k} b h h_{f}\left(d-\frac{h_{h_{f}}}{2}\right)$
2. If $M \leq M_{\mathrm{f}}$, neutral axis lies in the flange

$$
\begin{aligned}
& K=\frac{M}{f_{c k} b d^{2}} \\
& z=d\left[0.5+\sqrt{\left(0.25-\frac{K}{1.134}\right)}\right] \\
& A_{s}=\frac{M}{0.87 f_{y k} z}
\end{aligned}
$$

3. If $M>M_{\mathrm{f}}$, neutral axis lies in the web

Calculate $\beta_{f}=0.167 \frac{b_{w}}{b}+0.567 \frac{h_{h_{f}}}{d}\left(1-\frac{b_{w}}{b}\right)\left(1-\frac{h_{h_{f}}}{2 d}\right)$
Calculate $M_{b a l}=\beta_{f} f_{c k} b d^{2}$
Compare $M$ with $M_{\text {bal }}$
4. If $M \leq M_{\text {bal }}$, compression reinforcement is not required

$$
A_{s}=\frac{M+0.1 f_{c k} b_{w} d\left(0.36 d-h_{f}\right)}{0.87 f_{y k}\left(d-\frac{h_{f}}{2}\right)}
$$

5. If $M>M_{\text {bal }}$, compression reinforcement is required

$$
\begin{aligned}
& A_{s}^{\prime}=\frac{\left(M-M_{b a l}\right)}{0.87 f_{y k}\left(d-d^{\prime}\right)} \\
& A_{s}=\frac{0.167 f_{c k} b_{w} d+0.567 f_{c k} h_{f}\left(b-b_{w}\right)}{0.87 f_{y k}}+A_{s}{ }^{\prime}
\end{aligned}
$$

## Minimum and Maximum Area of Reinforcement (Ref. Section 9.2: MS EN 1992-1-1: 2010)

The minimum area of reinforcement is given as:
$A_{s, \min }=0.26\left(\frac{f_{c t m}}{f_{y k}}\right) b d$ but not less than $0.0013 b d$
and the maximum area of reinforcement is given as:
$A_{s, \max }=0.04 A_{c}=0.04 b h$

### 7.0 DESIGN FOR SHEAR

(Ref. Section 6.2: MS EN 1992-1-1: 2010)

## Members Requiring Design Shear Reinforcement

The following procedure can be use for determining vertical shear reinforcement.

1. Determine design shear force $V_{\mathrm{Ed}}$
2. Determine the concrete strut capacity, $V_{\mathrm{Rd}, \max }$ for $\cot \theta=1.0$ and $\cot \theta=2.5\left(\theta=45^{\circ}\right.$ and $\theta=22^{\circ}$, respectively), where:
$V_{R d, \max }=\frac{0.36 f_{c k} b_{w} d\left(1-\frac{f_{c k}}{250}\right)}{(\cot \theta+\tan \theta)}$
3. If $V_{\mathrm{Ed}}>V_{\mathrm{Rd}, \text { max }} \cot \theta=1.0$, redesign the section
4. If $V_{\mathrm{Ed}}<V_{\mathrm{Rd}, \max } \cot \theta=2.5$, use $\cot \theta=2.5$, and calculate the shear reinforcement as follows
$\frac{A_{s w}}{s}=\frac{V_{E d}}{0.78 f_{y k} d \cot \theta}=\frac{0.513 V_{E d}}{f_{y k} d}$
5. If $V_{\mathrm{Rd}, \max } \cot \theta=2.5<V_{\mathrm{Ed}}<V_{\mathrm{Rd}, \max } \cot \theta=1.0$
$\theta=0.5 \sin ^{-1}\left[\frac{V_{E d}}{0.18 b_{w} d f_{c k}\left(1-\frac{f_{c k}}{250}\right)}\right]$
Calculate shear link as
$\frac{A_{s w}}{s}=\frac{V_{E d}}{0.78 f_{y k} d \cot \theta}$
6. Calculate the minimum links required
$\frac{A_{s w}}{s}=\frac{0.08 b_{w} \sqrt{f_{c k}}}{f_{y k}}$
7. Calculate the additional longitudinal tensile force caused by the shear
$\Delta F_{t d}=0.5 V_{E d} \cot \theta$

## Procedure for Calculating Transverse Shear Reinforcement in Flanged Section

1. Calculate the longitudinal design shear stress, $v_{\mathrm{Ed}}$ at the web-flange interface:
$v_{E d}=\frac{\Delta F_{d}}{\left(h_{f} \cdot \Delta x\right)}$
where $\Delta F_{d}=\frac{\Delta M}{\left(d-\frac{h_{f}}{2}\right)} \times \frac{\left(\frac{b_{f}-b_{w}}{2}\right)}{b_{f}}$ and $\Delta M$ is the change in moment over the distance $\Delta x$
2. If $v_{\text {Ed }}$ is less than or equal to $0.4 f_{\text {ctd }}=0.4\left(f_{\text {ctk }} / 1.5\right)=0.27 f_{\text {ctk }}$, then no shear reinforcement is required. Proceed to Step 4.
3. If $v_{\text {Ed }}$ is more than $0.4 f_{\text {ctd }}=0.4\left(f_{\text {ctk }} / 1.5\right)=0.27 f_{\text {ctk }}$, check the shear stresses in the incline strut.

To prevent crushing of the concrete in the compressive struts the longitudinal shear stress is limited to:
$v_{E d} \leq \frac{0.4 f_{c k}\left(1-\frac{f_{c k}}{250}\right)}{\left(\cot \theta_{f}+\tan \theta_{f}\right)}$
The lower value of the angle $\theta_{\mathrm{f}}$ is first tried and if the shear stresses are too high the angle $\theta_{\mathrm{f}}$ is calculated from the following equation:
$\theta_{f}=0.5 \sin ^{-1}\left[\frac{v_{E d}}{0.2 f_{c k}\left(1-\frac{f_{c k}}{250}\right)}\right] \leq 45^{\circ}$
The permitted range of the values $\cot \theta_{\mathrm{f}}$ is recommended as follows:
$\begin{array}{ll}1.0 \leq \cot \theta_{\mathrm{f}} \leq 2.0 & \text { for compression flanges }\left(45^{\circ} \leq \theta_{\mathrm{f}} \leq 26.5^{\circ}\right) \\ 1.0 \leq \cot \theta_{\mathrm{f}} \leq 1.25 & \text { for tension flanges }\left(45^{\circ} \leq \theta_{\mathrm{f}} \leq 38.6^{\circ}\right)\end{array}$
4. Calculate the transverse shear reinforcement required as:
$\frac{A_{s f}}{s_{f}}=\frac{v_{E d} h_{f}}{0.87 f_{y k} \cot \theta_{f}}$

## Minimum Area of Reinforcement in the Flange

The minimum amount of transverse steel required in the flange is:
$A_{s, \min }=\frac{0.26 b h_{f} f_{c t m}}{f_{y k}}>0.0013 b h_{f} \mathrm{~mm}^{2} / \mathrm{m}$
where $b=1000 \mathrm{~mm}$

## Sections Not Requiring Design Shear Reinforcement

In those sections where $V_{\mathrm{Ed}} \leq V_{\mathrm{Rd}, \mathrm{c}}$ then no calculated shear reinforcement is required. The shear resistance of the concrete, $V_{\mathrm{Rd}, \mathrm{c}}$, in such situations is given by an empirical expression:
$V_{R d, c}=\left[0.12 k\left(100 \rho_{1} f_{c k}\right)^{1 / 3}\right] b_{w} d$
with a minimum value of:
$V_{R d, c}=\left[0.035 k^{3 / 2} f_{c k}^{1 / 2}\right] b_{w} d$
where
$k=\left(1+\sqrt{\frac{200}{d}}\right) \leq 2.0$ with d expressed in mm
$\rho_{1}=\left(\frac{A_{s l}}{b_{w} d}\right) \leq 0.02$
$A_{\mathrm{s} 1}=$ the area of tensile reinforcement that extends $\geq\left(l_{\mathrm{bd}}+d\right)$ beyond the section considered $b_{\mathrm{w}}=$ the smallest width of the section in tensile area (mm).

### 8.0 DEFLECTION

(Ref. Section 7.4: MS EN 1992-1-1: 2010)

The equations to calculate the basic span-effective depth ratios, to control deflection to a maximum of span/250 are given as:
$\frac{l}{d}=K\left[11+1.5 \sqrt{f_{c k}} \frac{\rho_{o}}{\rho}+3.2 \sqrt{f_{c k}}\left(\frac{\rho_{o}}{\rho}-1\right)^{3 / 2}\right] \quad$ if $\rho \leq \rho_{o}$
$\frac{l}{d}=K\left[11+1.5 \sqrt{f_{c k}} \frac{\rho_{o}}{\rho-\rho^{\prime}}+\frac{1}{12} \sqrt{f_{c k}} \sqrt{\frac{\rho^{\prime}}{\rho}}\right] \quad$ if $\rho>\rho_{\mathrm{o}}$.
where $l / d$ is the limiting span/depth
$K$ is the factor to take into account the different in structural system from Table 7.4 N
$\rho_{0}$ is the reference reinforcement ratio $=\sqrt{f_{c k}} 10^{-3}$
$\rho$ is the required tension reinforcement ratio $=\frac{A_{s, \text { req }}}{b d}$
$\rho^{\prime}$ is the required compression reinforcement ratio $=\frac{A_{s, r e q}{ }^{\prime}}{b d}$

Table 7.4N: Basic span/effective depth ratio (typical values for rectangular section for steel grade $f_{y \mathrm{yk}}=500 \mathrm{~N} / \mathrm{mm}^{2}$ and concrete class C30/35)

|  | Structural System | $\mathbf{K}$ | Basic span-effective depth ratio |  |
| :--- | :--- | :---: | :---: | :---: |
|  |  | Concrete highly <br> stressed, $\boldsymbol{\rho}=\mathbf{1 . 5 \%}$ | Concrete lightly <br> stressed, $\boldsymbol{\rho}=\mathbf{0 . 5 \%}$ |  |
| 1.Simply supported beam, one/two way <br> simply supported slab | 1.0 | 14 | 20 |  |
| 2.End span of continuous beam or one-way <br> continuous slab or two way spanning slab <br> continuous over one long side | 1.3 | 18 | 26 |  |
| 3.Interior span of beam or one way or two <br> way spanning slab | 1.5 | 20 | 30 |  |
| 4.Slab supported on columns without beam <br> (flat slab) based on longer span | 1.2 | 17 | 24 |  |
| 5.Cantilever | 0.4 | 6 | 8 |  |

The basic ratios are modified in particular cases as follows:
(i) For flange section where the ratio of the flange width to the web width exceeds 3 , the values should be multiplied by 0.8 .
(ii) For beam and slabs, other than flat slab, with spans exceeding 7 m , which support partitions liable to be damaged by excessive deflection, the values should be multiplied by 7/span.
(iii) Where more tension reinforcement is provided $\left(A_{\mathrm{s}}\right.$, prov $)$ than that calculated $\left(A_{\mathrm{s}}\right.$, req , multiply the values by $=$ $\frac{A_{s, \text { prov }}}{A_{s, \text { req }}}($ upper limit $=1.5)$.

### 9.0 CRACKING

(Ref. Section 7.3: MS EN 1992-1-1: 2010)

## General Consideration

(1) Cracking shall be limited to an extent that will not impair the proper functioning or durability of the structure or cause its appearance to be unacceptable.
(2) Cracking is normal in reinforced concrete structures subject to bending, shear, torsion or tension resulting from either direct loading or restraint or imposed deformations.
(3) Cracks may also arise from other causes such as plastic shrinkage or expansive chemical reactions within the hardened concrete. Such cracks may be unacceptably large but their avoidance and control lie outside the scope of this Section.
(4) Cracks may be permitted to form without any attempt to control their width, provided they do not impair the functioning of the structure

Note: The value of $w_{\max }$ for use in a Country may be found in its National Annex. The recommended values for relevant exposure classes are given in Table 7.1N.

Table 7.1N: Recommended values of $w_{\max }(\mathrm{mm})$

| Exposure Class | Reinforced Members and Prestressed Members without Unbounded Tendons | Prestressed Members with Bonded Tendons |
| :---: | :---: | :---: |
|  | Quasi permanent load combination | Frequent load combination |
| X0, XC1 | $0.4{ }^{1}$ | 0.2 |
| XC2, XC3, XC4 | 0.3 | $0.2^{2}$ |
| $\begin{aligned} & \hline \text { XD1, XD2, XS1, } \\ & \text { XS2, XS3 } \end{aligned}$ |  | Decompression |

Note 1: For X0, XC1 exposure classes, crack width has no influence on durability and this
limit is set to give generally acceptable appearance. In the absence of appearance conditions this limit may be relaxed.
Note 2: For these exposure classes, in addition, decompression should be checked under the quasi-permanent combination of loads.

## Minimum Reinforcement Area

Flexural cracking is generally controlled by providing a minimum area of tension reinforcement and limiting bar spacing or limiting bar sizes.
(a) Minimum reinforcement area
$A_{s, \min }=\frac{k_{c} k f_{c t, e f f} A_{c t}}{f_{y k}}$
where $\quad k_{\mathrm{c}}$ is the stress distribution coefficient ( 1.0 for pure tension, 0.4 for flexure)
$k$ is the non-linear stress distribution coefficient
$=1.0$ for webs with $h \leq 300 \mathrm{~mm}$ or flanges $<300 \mathrm{~mm}$ wide
$=0.65$ for webs $h \geq 800 \mathrm{~mm}$ or flanges $>800 \mathrm{~mm}$ wide (interpolate for intermediate values)
$f_{\mathrm{ct} \text {, eff }}$ is the tensile strength of concrete at time of cracking with a suggested minimum of $3 \mathrm{~N} / \mathrm{mm}^{2}$.
$A_{\mathrm{ct}}$ is the area of concrete within tensile zone - defined as that area which is in tension just before the initiation of the first crack.

## Control of Cracking without Direct Calculation

(b) Maximum spacing of reinforcement

Cracking due to loading is minimized by ensuring that the maximum spacing between longitudinal reinforcing bars in beam is limited to that given in Table 7.2 N .

Table 7.2N: Maximum bar spacing for crack control

| Steel stress <br> $\left(\mathbf{N} / \mathbf{m m}^{\mathbf{2}}\right)$ | Maximum bar spacing $(\mathbf{m m})$ |  |
| :---: | :---: | :---: |
|  | $\boldsymbol{w}_{\mathbf{k}}=\mathbf{0 . 3} \mathbf{~ m m}$ |  |

### 10.0 MOMENT AND SHEAR COEFFICIENT FOR CONTINUOUS BEAM

Approximate general solutions for the maximum bending moments and shearing forces in uniformly loaded beams of three or more spans are given in Table 3.5. This table is reproduced from BS 8110 Part 1: 1997.

Table 3.5: Moments and shear coefficients of continuous beam (Ref. BS 8110: Part 1: 1997)

| Position | At outer <br> support | Near <br> middle of <br> end span | At first <br> interior <br> support | At middle <br> of interior <br> spans | At interior <br> supports |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Bending moment | 0 | $+0.09 F L$ | $-0.11 F L$ | $+0.07 F L$ | $-0.08 F L$ |
| Shear force | $0.45 F$ | - | $0.6 F$ | - | $0.55 F$ |

Note: Values apply where characteristic variable load does not exceed characteristic permanent load and variations is span length do not exceed $15 \%$ of the longest span. ( $F$ is the total design load on span, and $L$ is the effective span)

## SIMPLIFIED CURTAILMENT RULES FOR BEAM

(Ref. "How to design concrete structures using Eurocode 2", The Concrete Centre, 2010)

Figure 1: Simplified detailing rules for beams

## Notes:

1. $\quad l$ is the effective length
2. $\quad a_{l}$ is the distance to allow for tensile force due to shear force $=z \cot \theta / 2$. Can conservatively taken as $1.125 d$
3. $l_{\mathrm{bd}}$ is the design anchorage length.
4. $\quad q_{\mathrm{k}} \leq g_{\mathrm{k}}$
5. Minimum of two spans required
6. Applies to uniformly distributed loads only.
7. The shortest span must be greater than or equal to 0.85 times the longest span
8. Applies where $15 \%$ redistribution has been used.

### 11.0 MOMENT AND SHEAR COEFFICIENT FOR SOLID SLAB

## Continuous One-way Slab

For slabs carrying uniformly distributed load and continuous over three or more nearly equal spans, approximate solution for the ultimate bending moments and shearing forces, are given in Table 3.12. This table is reproduced from BS 8110 Part 1: 1997.

Table 3.12: Ultimate moment and shear coefficients in continuous one way slab (Ref. BS 8110: Part 1: 1997)

|  | End support condition |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Pinned |  | Continuous |  |  |  |  |
|  | At outer <br> support | Near <br> middle <br> of end <br> span | At outer <br> support | Near <br> middle <br> of end <br> span | At first <br> interior <br> support | Middle <br> interior <br> spans | Interior <br> supports |
| Moment | 0 | $0.086 F L$ | $-0.04 F L$ | $0.075 F L$ | $-0.086 F L$ | $0.063 F L$ | $-0.063 F L$ |
| Shear | $0.4 F$ | - | $0.46 F$ | - | 0.6 F | - | $0.5 F$ |
| $L=$ Effective span <br> $F=$ Total ultimate load $=1.35 g_{\mathrm{k}}+1.5 q_{\mathrm{k}}$ |  |  |  |  |  |  |  |

## Two-way Simply Supported Slab

A slab simply supported on its four sides with no provision has been made to prevent lifting or to resist the torsion then the moment coefficient of Table 3.13 may be used and the maximum moments are given by:

$$
\begin{aligned}
& m_{s x}=\alpha_{s x} n l_{x}^{2} \\
& m_{s y}=\alpha_{s y} n l_{x}^{2}
\end{aligned}
$$

where $\quad n$ is the total ultimate load per unit area
$l_{\mathrm{x}}$ is the length of shorter side
$l_{\mathrm{y}}$ is the length of longer side
$\alpha_{\mathrm{sx}}$ and $\alpha_{\mathrm{sy}}$ are the moment coefficient from Table 3.13
Table 3.13: Bending moment coefficient for simply supported two-way slab (Ref. BS 8110: Part 1: 1997)

| $\boldsymbol{l}_{\mathbf{y}} / \boldsymbol{l}_{\mathbf{x}}$ | $\mathbf{1 . 0}$ | $\mathbf{1 . 1}$ | $\mathbf{1 . 2}$ | $\mathbf{1 . 3}$ | $\mathbf{1 . 4}$ | $\mathbf{1 . 5}$ | $\mathbf{1 . 7 5}$ | $\mathbf{2 . 0}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\alpha_{\mathrm{sx}}$ | 0.062 | 0.074 | 0.084 | 0.093 | 0.099 | 0.104 | 0.113 | 0.118 |
| $\alpha_{\mathrm{sy}}$ | 0.062 | 0.061 | 0.059 | 0.055 | 0.051 | 0.046 | 0.037 | 0.029 |

## Two-way Restrained Slab

When the slab are provided with different edge conditions like fixed or continuous edges, the maximum moments per unit width are given by:

$$
\begin{aligned}
& m_{s x}=\beta_{s x} n l_{x}^{2} \\
& m_{s y}=\beta_{s y} n l_{x}^{2}
\end{aligned}
$$

where $\quad n$ is the total ultimate load per unit area
$l_{\mathrm{x}}$ is the length of shorter side
$l_{y}$ is the length of longer side
$\beta_{\mathrm{sx}}$ and $\beta_{\mathrm{sy}}$ are the moment coefficients from Table 3.14

Table 3.14: Bending moment coefficients for two-way restrained slab (Ref. BS 8110: Part 1: 1997)

## Shear Force for Two-way Restrained Slab and Actions on Supporting Beams

The design shear forces of slab or loads on beams which supported the slabs can be evaluated using the equations below:
$v_{s x}=\beta_{v x} n l_{x}$
$v_{s y}=\beta_{s y} n l_{x}$
where $n$ is the total ultimate load per unit area
$l_{\mathrm{x}}$ is the length of shorter side
$\beta_{\mathrm{vx}}$ and $\beta_{\mathrm{vy}}$ are the shear coefficients from Table 3.15
Table 3.15: Shear force coefficients for restrained two-way slab (Ref. BS 8110: Part 1: 1997)

| Type of panel and location | $\beta_{\mathrm{vx}}$ for values of $l_{\mathrm{y}} / l_{\mathrm{x}}$ |  |  |  |  |  |  |  | $\beta_{\mathrm{vy}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 | 1.75 | 2.0 |  |
| Four edges continuous Continuous edge | 0.33 | 0.36 | 0.39 | 0.41 | 0.43 | 0.45 | 0.48 | 0.50 | 0.33 |
| One short edge discontinuous Continuous edge Discontinuous edge | 0.36 | 0.39 | 0.42 | 0.44 | 0.45 | 0.47 | 0.50 | 0.52 | $\begin{aligned} & 0.36 \\ & 0.24 \end{aligned}$ |

| Three edges discontinuous (one short edge discontinuous) <br> Continuous edge <br> Discontinuous edge | $0.29$ | $0.33$ | $0.36$ | $0.38$ | $0.40$ | $0.42$ | $0.45$ | $0.48$ | $\begin{aligned} & 0.45 \\ & 0.30 \\ & \hline \end{aligned}$ |
| Four edges discontinuous Discontinuous edge | 0.33 | 0.36 | 0.39 | 0.41 | 0.43 | 0.45 | 0.48 | 0.50 | 0.33 |

### 12.0 CRACKING RULES FOR SLAB

## (Ref. Section 9.3: MS EN 1992-1-1: 2010)

To resist cracking of the concrete slabs, EC2 specify details such as minimum area of reinforcement required in a section and limits to the maximum and minimum spacing of bar.
(a) The minimum area of principal reinforcement is $A_{s, \text { min }}=\frac{0.26 f_{c t m} b_{t} d}{f_{y k}}$ but not less than $0.0013 b_{\mathrm{t}} d$, where $b_{\mathrm{t}}$ is the mean width of the tension zone.
(b) The minimum area of secondary reinforcement is $20 \% A_{\mathrm{s}}$. In areas near support, transverse reinforcement is not necessary where there is no transverse bending moment.
(c) The spacing of principal reinforcement bars should not exceed three times the overall depth of slab (3h) or 400 mm whichever is the lesser. For secondary reinforcement the spacing should not exceed 3.5 h or 450 mm whichever the lesser. These rules apply for slabs not exceeding 200 mm thick.

### 13.0 SIMPLIFIED CURTAILMENT RULES FOR SLAB

(Ref. "How to design concrete structures using Eurocode 2", The Concrete Centre, 2010)

(a) Simply Supported

(b) Continuous

Figure 2: Simplified detailing rules for slabs

## Notes

1. $\quad l$ is the effective length
2. $l_{\mathrm{bd}}$ is the design anchorage length.
3. $\quad q_{\mathrm{k}} \leq 1.25 g_{\mathrm{k}}$ and $q_{\mathrm{k}} \leq 5 \mathrm{kN} / \mathrm{m}^{2}$
4. Minimum of two spans required
5. Applies to uniformly distributed loads only.
6. The shortest span must be greater than or equal to 0.85 times the longest span
7. Applies where $20 \%$ redistribution has been used.

### 14.0 PRESTRESSED MEMBERS AND STRUCTURES

## Limitation of Concrete Stress (Ref. Section 5.10.2.2: MS EN 1992-1-1: 2010)

(1) Local concrete crushing or splitting at the end of pre- and post-tensioned members shall be avoided.
(2) Local concrete crushing or splitting behind post-tensioning anchors should be avoided in accordance with the relevant European Technical Approval.
(3) The strength of concrete at application of or transfer of prestress should not be less than the minimum value defined in the relevant European Technical Approval.
(4) If prestress in an individual tendon is applied in steps, the required concrete strength may be reduced. The minimum strength $f_{\mathrm{cm}}(t)$ at the time $t$ should be $k_{4}[\%]$ of the required concrete strength for full prestressing given in the European Technical Approval. Between the minimum strength and the required concrete strength for full prestressing, the prestress may be interpolated between $k_{5}[\%]$ and $100 \%$ of the full prestressing.

Note: The values of $k_{4}$ and $k_{5}$ for use in a Country may be found in its National Annex. The recommended value for $k_{4}$ is 50 and for $k_{5}$ is 30 .
(5) The concrete compressive stress in the structure resulting from the prestressing force and other loads acting at the time of tensioning or release of prestress, should be limited to:
$\sigma_{\mathrm{c}} \leq 0.6 \mathrm{f}_{\mathrm{ck}}(t)$
where $f_{\mathrm{ck}}(t)$ is the characteristic compressive strength of the concrete at time $t$ when it is subjected to the prestressing force. The limitation for both service and transfer condition are summarised in Table 1.

For pretensioned elements the stress at the time of transfer of prestress may be increased to $k_{6} \cdot f_{\mathrm{ck}}(t)$, if it can be justified by tests or experience that longitudinal cracking is prevented.

Note: The value of $k_{6}$ for use in a Country may be found in its National Annex. The recommended value is 0.7.
If the compressive stress permanently exceeds $0.45 f_{\text {ck }}(t)$ the non-linearity of creep should be taken into account.
Table 1: Limitation of Concrete Stress

| Stresses | Loading Stage |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Transfer |  |  |  |  |
|  | Symbol | Value or Equation | Symbol | Value or Equation |  |
| Compressive | $f_{\mathrm{ct}}$ | $0.6 f_{\mathrm{ck}}(t)$ | $f_{\mathrm{cs}}$ | $0.6 f_{\mathrm{ck}}$ |  |
| Tensile | $f_{\mathrm{ct}}$ | $f_{\mathrm{ctm}}$ | $f_{\mathrm{ts}}$ | 0 |  |

## 15. DESIGN OF COLUMNS

## Slenderness ratio (Ref. Section 5.8.3.2 MS EN 1992:2010)

The slenderness ratio of a column bent about an axis is given by

$$
\lambda=l_{0} / i=l_{0} /(I / A)^{1 / 2}
$$

where
$l_{0} \quad=\quad$ the effective length of the column
$i=$ the radius of gyration about the axis considered
$I=$ the second moment of area of the section about the axis
$A=$ the cross-sectional area of the column
For columns in regular frames, an effective length can be determined in the following way:
Braced columns

$$
l_{o}=0.5 l \sqrt{\left(1+\frac{k_{1}}{0.45+k_{1}}\right)\left(1+\frac{k_{2}}{0.45+k_{2}}\right)}
$$

Unbraced columns
$l_{o}=l \cdot \max \left\{\sqrt{\left(1+10 \cdot \frac{k_{1} \cdot k_{2}}{k_{1}+k_{2}}\right)} ;\left(1+\frac{k_{1}}{1+k_{1}}\right) \cdot\left(1+\frac{k_{2}}{1+k_{2}}\right)\right\}$
where
$k_{1}, k_{2} \quad$ are the relative flexibilities of rotational restraints at ends 1 and 2 respectively
$k=$ column stiffness $/ \Sigma$ beam stiffness $=(E I / /)_{\text {column }} / \Sigma 2(E I /)_{\text {beam }}$
$l$ is the clear height of compression member between end restraints at each end
Note: $k=0$ is the theoretical limit for rigid rotational restraint, and $k=\infty$ represents the limit for no restraint at all. Since fully rigid restraint is rare in practise, a minimum value of 0,1 is recommended for $k_{1}$ and $k_{2}$.

## Slenderness Limit (Ref. Section 5.8.3.1 MS EN 1992:2010)

The upper limit on the slenderness ratio of a single column below which second order may be ignored is given by:

$$
\lambda_{\lim }=20 \cdot A \cdot B \cdot C / \sqrt{n}
$$

where
$A=1 /\left(1+0.2 \varphi_{\text {eff }}\right) \quad: \varphi_{\text {eff }}=$ effective creep ratio
$B=(1+2 \omega)^{0.5} \quad: \omega=A_{s} f_{y d} /\left(A_{d} f_{c d}\right)$
$C=1.7-r_{m} \quad: r_{m}=M_{o l} / M_{o 2}$
$n=N_{\mathrm{Ed}} /\left(A_{\mathrm{f}} f_{\mathrm{cd}}\right)$
$N_{\mathrm{Ed}}=$ the design ultimate axial load in the column
$M_{\mathrm{o} 1}, M_{\mathrm{o} 2}$ are the first order moments at the end of the column with $\left|M_{\mathrm{o} 2}\right| \geq\left|M_{\mathrm{o} 1}\right|$
$f_{\mathrm{yd}}=$ the design yield strength of the reinforcement
$f_{\mathrm{cd}}=$ the design compressive strength of concrete
If $\varphi_{e f f}, \omega$, and $r_{m}$ are not known, $A=0.7, B=1.1$ and $C=0.7$ may be used.
The following conditions apply to the value of $C$ :
(a) If the end moments, $M_{\mathrm{o} 1}$ and, $M_{\mathrm{o} 2}$, give rise tension on the same side of the column, $r_{\mathrm{m}}$ should be taken as positive from which it follows that $C \leq 1.7$.
(b) If the column is in a state of double curvature, then $r_{\mathrm{m}}$ should be taken as negative from which it follows that $C>1.7$.
(c) For braced members in which the first order moment arise only from or predominantly due to imperfections or transverse loading, $r_{\mathrm{m}}$ should be taken as $1.0(C=0.7)$
(d) For unbraced member in general, $r_{\mathrm{m}}$ should be taken as $1.0(C=0.7)$

If the actual slenderness ratio is less than the calculated value of $\lambda_{\lim }$ then the column can be treated as short. Otherwise the column must be treated as slender and second order effects must be accounted for in the design of the column.

## Longitudinal Reinforcement (Ref. Section 9.5.2 MS EN 1992:2010)

The minimum area of longitudinal reinforcement required in column is given by

$$
A_{\mathrm{s}, \min }=0.10 N_{\mathrm{Ed}} / f_{\mathrm{yd}} \text { or } 0.002 A_{\mathrm{c}} \text { whichever the greater. }
$$

The recommended minimum diameter of longitudinal reinforcement in columns is 12 mm . A minimum of four bars required in a rectangular column and six bars in a circular column.

The maximum area of reinforcement should not exceed $4 \%$ outside lap locations. However at laps $8 \%$ is permitted.

## Transverse Reinforcement (Ref. Section 9.5.3 MS EN 1992:2010)

The diameter of links should not be less than 6 mm or one-quarter of the diameter of the largest longitudinal bar. The maximum spacing of links in columns should not exceed.

- 20 times the minimum diameter of the longitudinal bars
- the lesser dimension of the column
- 400 mm

At the distance within the larger dimension of the column above or below a beam or slab and near lapped joints these spacing should be reduced by a factor of 0.6. Every longitudinal bar or bundle of bars placed in a corner should be held by transverse reinforcement. No bar within compression zone should be further than 150 mm from a restrained bar.

## Design Moments (Ref. Section 5.8.7 MS EN 1992:2010)

The design moment is;

$$
M_{\mathrm{Ed}}=M_{0 \mathrm{Ed}}+M_{2}
$$

where:
$M_{0 \mathrm{Ed}} \quad=$ The $1^{\text {st }}$. order moment including the effect of imperfection
$M_{2}=$ The nominal $2^{\text {nd }}$. order moment.

For braced slender column:

$$
M_{\mathrm{Ed}}=\operatorname{Max}\left\{M_{02}, M_{0 \mathrm{E}}+M_{2}, M_{01}+0.5 M_{2}\right\}
$$

For unbraced slender column;

$$
M_{\mathrm{Ed}}=\operatorname{Max}\left\{M_{01}+M_{2,}, M_{01}+M_{2}\right\}
$$

where,

$$
M_{01}=\operatorname{Min}\left\{\left|M_{\mathrm{top}}\right|,\left|M_{\mathrm{bot}}\right|\right\}+N_{\mathrm{Ed}} \cdot e_{1}
$$

$$
M_{02}=\operatorname{Max}\left\{\left|M_{\mathrm{top}}\right|,\left|M_{\mathrm{bot}}\right|\right\}+N_{\mathrm{Ed}} \cdot e_{1}
$$

$N_{\mathrm{Ed}}=$ The ultimate axial load
$e_{1}=l_{\mathrm{o}} / 400$ units to be in mm
$M_{\mathrm{top}}, M_{\mathrm{bot}}=$ Moments at the top and bottom of the column

$$
M_{0 \mathrm{E}}=0.6 M_{02}+0.4 M_{01} \geq 0.4 M_{02}
$$

$M_{\mathrm{o} 1}$ and $M_{\mathrm{o} 2}$ should have the same sign if they give tension on the same side, otherwise opposite sign.

$$
\begin{aligned}
M_{2} & =\text { The nominal second order moment }=N_{\mathrm{Ed}} \mathrm{e}_{2} \\
e_{2} & =\text { The deflection }=(1 / r) l_{\mathrm{o}}^{2} / c \\
l_{o} & =\text { The effective length } \\
c & =\text { A factor depending on the curvature distribution, normally } \pi^{2} \approx 10 \\
1 / r & =\text { The curvature }=K_{r} \cdot K_{\varphi} \cdot 1 / r_{o}
\end{aligned}
$$

$$
K_{r}=\text { axial load correction factor }=\left(n_{\mathrm{u}^{-}} n\right) /\left(n_{\mathrm{u}^{-}}-n_{\mathrm{bal}}\right)<1
$$

$$
\text { where, } n=N_{\mathrm{Ed}} /\left(A_{\mathrm{f}} f_{\mathrm{cd}}\right), \quad n_{\mathrm{u}}=1+w, \quad n_{\text {bal }}=0.4
$$

$$
w=A_{\mathrm{s}} f_{\mathrm{yd}} /\left(A_{\mathrm{c}} f_{\mathrm{cd}}\right)
$$

$K_{\varphi}=$ creep correction factor $=1+\beta \varphi_{\mathrm{ef}} \geq 1$
where, $\varphi_{\varepsilon \mathrm{f}}=$ effective creep ratio $=j M_{o E q p} / M_{o E d}$

$$
\begin{gathered}
=0 \text { if }(\varphi<2, M / N>h, 1<75) \\
\beta=0.35+f_{\mathrm{ck}} / 200-\lambda / 150 \quad(\lambda=\text { slenderness ratio }) \\
l / r_{\mathrm{o}}=\varepsilon_{\mathrm{yd}} /(0.45 d)=\left(f_{\mathrm{yd}} / E_{s}\right) /(0.45 d)=
\end{gathered}
$$

Short column can be design ignoring second order effects and therefore the ultimate design moment, $M_{\mathrm{Ed}}=M_{2}$

## Biaxial Bending (Ref. Section 5.8.9 MS EN 1992:2010)

Biaxial bending need not be considered if
(a) $\lambda_{y} / \lambda_{z} \leq 2$ and $\lambda_{z} / \lambda_{y} \leq 2$, and
(b) $\quad\left[\left(e_{\mathrm{y}} / h_{\text {eq }}\right) /\left(e_{\mathrm{z}} / b_{\text {eq }}\right)\right] \leq 0.2 \quad$ or $\quad\left[\left(e_{z} / b_{\text {eq }}\right) /\left(e_{\mathrm{y}} / h_{\text {eq }}\right)\right] \leq 0.2$
where
$b, h$ are the width and depth of a section
$b_{\text {eq }}=i_{\mathrm{y}} \cdot \sqrt{ } 12$ and $h_{\mathrm{eq}}=i_{\mathrm{z}} . \sqrt{ } 12$ for an equivalent rectangular section
$\lambda_{y}, \lambda_{z}$ are the slenderness ratio with respect to $y$ - and $z$ - axis respectively
$e_{\mathrm{y}}=M_{\mathrm{Edz}} / N_{\mathrm{Ed}}$; eccentricity along y-axis
$e_{\mathrm{z}}=M_{\mathrm{Edy}} / N_{\mathrm{Ed}} ;$ eccentricity along z-axis
$M_{\text {Edy }}$ is the design moment about y-axis. Including second order moment
$M_{\text {Edz }}$ is the design moment about z-axis. Including second order moment
$N_{\text {Ed }}$ is the design value of axial load in the respective load combination

Figure 1: Definition of eccentricities $e_{\mathrm{y}}$ and $e_{\mathrm{z}}$

If the above conditions are not fulfilled, biaxial bending should be taken into account including the second order effects in each direction. The following simplified criterion may be used:

$$
\left(\frac{M_{E d z}}{M_{R d z}}\right)^{a}+\left(\frac{M_{E d y}}{M_{R d y}}\right)^{a} \leq 1.0
$$

where
$M_{\text {Rdy }} \quad$ is the moment resistance in y-axis. Including second order moment
$M_{\mathrm{Rdz}} \quad$ is the moment resistance in z-axis. Including second order moment
$a$ is the exponent;
for circular and elliptical cross section: $a=2$
for rectangular cross sections :

| $N_{\mathrm{Ed}} / N_{\mathrm{Rd}}$ | 0.1 | 0.7 | 1.0 |
| :---: | :---: | :---: | :---: |
| $a$ | 1.0 | 1.5 | 2.0 |

with linear interpolation for intermediate values
$N_{\mathrm{Rd}}=A_{\mathrm{c}} f_{\mathrm{cd}}+A_{\mathrm{s}} f_{\mathrm{yd}}$, design axial resistance of section
$A_{\mathrm{c}}$ is the gross area of the concrete section
$A_{\mathrm{s}}$ is the area of longitudinal reinforcement
Biaxial bending column may be design using the method presented in BS 8110. The method specifies that a column subjected to an ultimate load $N_{\mathrm{Ed}}$ and moments $M_{\mathrm{z}}$ and $M_{\mathrm{y}}$ may be designed for a single axis bending but with an increase moment as follows;
(a) if $M_{\mathrm{z}} / h^{\prime} \geq M_{\mathrm{y}} / b^{\prime}$
then the increased single axis design moment is

$$
M_{\mathrm{z}}^{\prime}=M_{\mathrm{z}}+\beta\left(h^{\prime} / b^{\prime}\right) M_{\mathrm{y}}
$$

(b) if $M_{\mathrm{z}} / h^{\prime} \leq M_{\mathrm{y}} / b^{\prime}$,
then the increased single axis design moment is

$$
M_{\mathrm{y}}^{\prime}{ }^{\prime}=M_{\mathrm{y}}+\beta\left(b^{\prime} / h^{\prime}\right) M_{\mathrm{z}}
$$

The coefficient $\beta$ is specified in Table 1 or can be obtained from the equation

$$
\beta=1-\left(N_{\mathrm{Ed}} / b h f_{\mathrm{ck}}\right)
$$

Table 1: Values of coefficient $\beta$ for biaxial bending

| $N_{\mathrm{Ed}} / b h f_{\mathrm{ck}}$ | 0 | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | $\geq 0.75$ |

### 16.0 FRAME ANALYSIS

## Method of Analysis (Ref. Section 5.1 MS EN 1992:2010)

Code of practices permit the use of approximate analysis techniques in which the structure can be considered as a series of sub-frames. EC 2 does not specifically describe the extent to which various columns and beams are included in the sub-frames. The methods of sub-frames analysis discussed here are based on BS 8110.
i. One-level Sub-frame

Each sub-frame may be taken to consist of the beams at one level together with the columns above and below. The ends of the columns remote from the beams may generally be assumed to be fixed unless the assumption of a pinned end is clearly more reasonable (for example, where a foundation detail is considered unable to develop moment restraint)

Sub-frame for analysis of beams and columns

## ii. Two-points Sub-frame

The moments and forces in certain individual beam may be found by considering a simplified sub-frame consisting only of that beam, the columns attached to the end of that beam and the beams on either side, if any. The column and beam ends remote from the beam under consideration may generally be assumed to be fixed unless the assumption of pinned is clearly more reasonable. The stiffness of the beams on either side of the beam considered should be taken as half their actual values if they are taken to be fixed at their outer ends.

Sub-frame for analysis of individual beam

## iii. Continuous beam and one-point sub-frame

The moments and forces in the beams at one level may also be obtained by considering the beams as a continuous beam over supports providing no restraint to rotation.

Continuous beam for analysis of beams
The ultimate moments for column may be calculated by simple moment distribution procedures, on the assumption that the column and beam ends remote from the junction under consideration are fixed and that the beams posses half their actual stiffness. The arrangement of the design ultimate variable loads should be such as to cause the maximum moment the column.

One-point sub-frames for analysis of columns

## Load Cases and Combination (Ref. Section 5.1.3 MS EN 1992:2010)

Separate actions or loads must be applied to the structure in appropriate directions and various types of actions combined with partial safety factors selected to cause the most severe design condition for the member under consideration. In general the following combination of actions should be investigated.

Load set 1: Adjacent or alternate spans loaded
i. any two adjacent spans carrying the design variable and permanent loads $\left(1.35 G_{\mathrm{k}}+1.5 Q_{\mathrm{k}}\right)$,: all other spans carrying only the design permanent $\operatorname{load}\left(1.35 G_{\mathrm{k}}\right)$
ii. alternate span carrying the design variable and permanent load $\left(1.35 G_{\mathrm{k}}+1.5 Q_{\mathrm{k}}\right)$, other spans carrying only the design permanent loads $\left(1.35 G_{\mathrm{k}}\right)$

Load set 2: Alternate or all spans loaded
i. alternate span carrying the design variable and permanent load $\left(1.35 G_{\mathrm{k}}+1.5 Q_{\mathrm{k}}\right)$, other spans carrying only the design permanent loads $\left(1.35 G_{\mathrm{k}}\right)$
ii. all span carrying the design variable and permanent loads $\left(1.35 G_{\mathrm{k}}+1.5 Q_{\mathrm{k}}\right)$.

Load Set 1 is the recommended arrangement given by EC2: Section 5.1.3. Malaysian National Annex allows the use of Load Set 2 which requires only three load cases that need to be assessed.

## Analysis of Frame for Lateral Loads

The two popular approximate method of analysis for lateral loads are portal method and cantilever method.
In the portal method, the frame is theoretically divided into independent portals. The shear in each storey is assumed to be divided between the bays in proportion to their spans. The shear in each bay is then divided equally between the columns. The column end moments are the column shear multiplied by one-half the column height. Beam moments balance the column moments. The external column only resist axial load which is found by dividing the overturning moment at any level by the width of the building.

In cantilever method the axial loads in column are assumed to be proportion to the distance from the centre of gravity of the frame. It is also usual to assume that all the column in a storey are of equal cross-sectional area and the point of contraflexure are located at the mid-points of all columns and beams.

## Calculation of Wind Load

Three procedures are specified in MS 1553: 2002 for the calculation of wind pressures on buildings: the simplified procedure, limited in application to buildings of rectangular in plan and not greater than 15.0 m high; analytical procedure, limited to regular buildings that are not more than 200 m high and structure with roof spans less than 100 m ; and the wind tunnel procedure, used for complex buildings.

### 17.0 DESIGN OF FOUNDATIONS

## (a) Design of pad footing

Thickness and size of footing
The total area at the base of the footing is determined from the point of view of the safe bearing capacity of soil. The thickness of footing is generally based on consideration of shear and flexure, which are critical near the column location.

## Design for flexure

The footing base slab bends upward into a saucer-like shape on account of the soil pressure from below. The critical section of bending is at the face of the column. The moment is taken on a section passing completely across the footing and is due to the ultimate loads on one side of the section. The moment and shear forces should be assessed using STR combination:

$$
N=1.35 G_{\mathrm{k}}+1.5 Q_{\mathrm{k}} \quad \text { STR combination } 1 \text { (Exp. 6.10 MS EN 1990) }
$$

## Check for shear (Ref. Section 6.4 MS EN 1992:2010)

Footing may fail in shear as beam shear or punching shear at the location shown in Figure 1

Figure 1: Location of critical shear section and perimeter

## Vertical shear

The critical section for vertical shear is at distance $d$ from the face of the column. The vertical shear force is the sum of the loads acting outside the section. If the design shear force $V_{E d}$ is less than the concrete shear resistance $V_{\text {Rd, }}$ no shear reinforcement is required.

## Punching shear

The critical section for punching shear is at a perimeter $2 d$ from the face of column. The punching shear force is the sum of the loads outside the critical perimeter. The shear stress is $v_{\mathrm{Ed}}=V_{\mathrm{Ed}} / u d$ where $u$ is the critical perimeter. If the shear stress $v_{\mathrm{Ed}}$ is less than the concrete shear resistance $v_{\mathrm{Rd}, \mathrm{c}}$ no shear reinforcement is required. The maximum punching shear at the column face must not exceed the maximum shear resistance $V_{\text {Rdmax }}$.

Punching shear resistance can be significantly reduced in the presence of a coexisting bending moment, $M_{\mathrm{Ed}}$, transmitted to the foundation. To allow for the adverse effect of the moment, which gives rise to a non-uniform distribution of shear around the control perimeter Clause 6.4.3(3) of EC2 gives the design shear stress to be used in punching shear calculaton as;

$$
v_{\mathrm{Ed}}=\beta \frac{V_{\mathrm{Ed}}}{u_{\mathrm{i}} d}
$$

where

| $\beta$ | $=$ factor used to include the effect of eccentrict loads |
| ---: | :--- |
|  | and bending moments |
|  | $=1+k \frac{M_{\mathrm{Ed}}}{V_{\mathrm{Ed}}} \frac{u_{1}}{W_{1}}$ |
| $k$ | $=$ coefficient dependent on the ratio between the column |
| dimension $\left(c_{1}\right.$ and $\left.c_{2}\right)$. |  |

$u_{1}=$ the length of basic control perimeter
$W_{1}=$ function of the basic control perimeter corresponds
to the distribution of shear
$=0.5 c_{1}^{2}+c_{1} c_{2}+4 c_{2} d+16 d^{2}+2 \pi d c_{1}$

Figure 11.5: Shear distribution due to an unbalanced moment

## Cracking and detailing requirements

Use the rules for slabs design or section 9.3 of MS EN 1992:2010

## (b) Design of Pile Foundation

## Determination of piles number and spacing

The number of piles required is determined based on the requirement that the pile load should not exceed the single pile capacity. Piles are usually arranged symmetrically with respect to the column axis. The pile loads are calculated as follows.
(i). Foundation subject to axial load only.

$$
F_{a}=\frac{(N+W)}{n}
$$

(ii). Foundation subject to axial load and moment

$$
F_{a i}=\frac{(N+W)}{n} \pm \frac{M x_{i}}{I_{y}}
$$

## Design of pile cap

## Size and thickness

The size and thickness of pile cap depends on the number of piles used, the arrangement of piles and the shape of pile cap.

## Main reinforcement

Pile caps are design either using bending theory or using the truss analogy.

## Design for shear

The shear capacity of a pile cap should be checked at the critical section taken to be $20 \%$ of the pile diameter inside the face of the pile. The whole of the force from the piles with centers lying outside this line should be considered.

In determining the shear resistance, shear enhancement may be considered such that the shear capacity of the concrete may be increase to $v_{c} \times 2 d / a$ where $a_{v}$ is the distance from the face of the column to the critical section. Where the spacing of the piles is less than or equal to three times the pile diameter, this enhancement may be applied across the whole critical section; otherwise it may be applied to strips of width of three times the pile diameter located central to each pile.

Where the spacing of the piles exceeds three times the pile diameter then the pile cap should be checked for punching shear on the perimeter shown in Figure 2. The shear force at the column face should be checked to ensure that it is less than $0.5 v_{1} f_{\mathrm{cd}} u d=0.5 v_{1}\left(f_{\mathrm{ck}} / 1.5\right) u d$ where u is the perimeter of the column and the strength reduction factor, $v_{1}=0.6\left(1-f_{\mathrm{ck}} / 250\right)$.

### 18.0 DESIGN OF RETAINING WALLS

## Stability analysis

The lateral force due to earth pressure constitutes the main force acting on the retaining wall, tending to make it overturn, slide and settle. So the safety of the wall depend on it stability against these three modes of failure under the ultimate limit state (EQU, STR and GEO) as defined in MS EN 1990:2010.

Three sets of load combinations must be considered at the ultimate limit state. The first two combinations will be used for consideration of both structural failure, STR, and geotechnical failure, GEO. The third combination must be taken when considering possible loss of equilibrium (EQU) of the structure such as overturning. The partial safety factors to be used for these three combinations are given in Table 1.

Table 1: Partial safety factor at the ultimate limit state

| Persistent or transient design situation | Permanent actions |  | Leading variable | Accompanying variable action |
| :---: | :---: | :---: | :---: | :---: |
|  | Unfavourable | Favourable | Unfavourable | Unfavourable |
| (a) For consideration of structural or geotechnical failure: combination 1 (STR \& GEO) | 1.35 | 1.00 | $\begin{gathered} 1.50 \\ (0 \text { if } \\ \text { favourable }) \end{gathered}$ | $\begin{gathered} 1.50 \\ (0 \text { if favourable) } \end{gathered}$ |
| (b) For consideration of structural or geotechnical failure: combination 2 (STR \& GEO) | 1.00 | 1.00 | $\begin{gathered} 1.30 \\ (0 \text { if } \\ \text { favourable }) \end{gathered}$ | $\begin{gathered} 1.30 \\ \text { (0 if favourable) } \end{gathered}$ |
| (c) For checking static equilibrium (EQU) | 1.10 | 0.90 | $\begin{gathered} 1.50 \\ (0 \text { if } \\ \text { favourable }) \end{gathered}$ | 1.50 (0 if favourabl e) |

## Overturning

A partial safety factor of 0.9 is applied to the permanent vertical load $\Sigma V_{\mathrm{k}}$ (weight of wall + weight of soil) if its effect is 'favourable'. The 'unfavourable' effects of the permanent earth pressure loading $H_{\mathrm{k}}$ at the rear face of the wall are multiplied by a partial safety factor of 1.1. The 'unfavourable' effects of the variable surcharge loading, if any, are multiplied by a partial safety factor of 1.5 . The stability requirement against overturning then become,

$$
0.9\left(\Sigma V_{\mathrm{k}} x\right) \geq \quad \gamma_{\mathrm{f}} H_{\mathrm{k}} y
$$

## Sliding

A partial safety factor of $\gamma_{\mathrm{f}}=1.0$ is applied to the permanent vertical load $\Sigma V_{\mathrm{k}}$ if its effect is 'favourable' (i.e. contribute to the sliding resistance) and the 'unfavourable" effects of the permanent earth and surcharge pressures at the rear face of the wall are multiplied by partial safety factor of $\gamma_{\mathrm{f}}=1.35$ and 1.5 respectively. Thus, if the coefficient of friction between base and soil is $\mu$, the stability requirement against sliding then become,

$$
\mu\left(\gamma_{\mathrm{f}} \Sigma V_{\mathrm{k}}\right) \geq \gamma_{\mathrm{f}} H_{\mathrm{k}}
$$

## Settlement

The bearing pressure is then given by, $\quad p=\Sigma N / A \pm \Sigma M / Z$. The maximum bearing pressure must be less than or equal to the soil bearing capacity. Two sets of load combinations must be considered at the ultimate limit state.

For load combination 1, the moment due to the horizontal load on the maximum bearing pressure at the toe of the wall is 'unfavourable' whilst the moments of the weight of the wall and the earth acting on the heel of the wall act in the opposite sense and are thus 'favourable'. Hence the partial safety factor for the lateral earth
pressure and lateral surcharge are 1.35 and 1.5 respectively, whilst the partial safety factor for the effect of weight of wall and soil is 1.0 and the partial safety factor for the weight of surcharge is 0 .

For load combination 2, the partial safety factor for permanent action is 1.0 for both 'unfavourable' and 'favourable' effects and the partial safety factor for variable action is 1.3 and 0 for unfavourable and favourable effects respectively.

## Element design and detailing

The three elements of the retaining wall, ie stem, toe slab and heel slab have to be designed as cantilever slabs to resist the designed moments and shear forces.

The stem is designed to resist the moment caused by the force $\gamma_{f} H_{f}$, with $\gamma_{f}$ values taken for load combination 1 if this load combination is deemed to be critical. The flexural reinforcement is provided near the rear face of the stem, and may be curtailed in stages for economy.

In the case of toe slab, the net pressure is obtained by deducting the weight of the concrete in the toe slab from the upward acting soil pressure. The net pressure acts upward and the flexural reinforcement has to be provided at the bottom of toe slab.

The heel slab must be designed to resist the moment due to downward pressure from the weight of the retained earth (plus surchage, if any) and concrete slab. Since the net pressure acts downward, the flexural reinforcement has to be provided at the top of the heel slab.

The partial safety factor $\gamma_{\mathrm{f} 1}, \gamma_{\mathrm{f} 2}$ and $\gamma_{\mathrm{f} 3}$ should be taken to provide a combination which gives the critical designed conditions i.e the worst of combination 1 and 2 . Temperature and shrinkage reinforcement should be provided transverse to the main reinforcement.
