

# **Engineering Economics**

Rate of Return Analysis

## Outcome of Today's Lecture

---

- ▶ **After completing this lecture...**
- ▶ **The students should be able to:**
- ▶ Evaluate project cash flows with the internal rate of return measure
- ▶ Plot a project's present worth against the interest rate
- ▶ Use an incremental rate of return analysis to evaluate competing alternatives

# Techniques for Cash Flow Analysis

---

- ▶ Present Worth Analysis
- ▶ Annual Cash Flow Analysis
- ▶ **Rate of Return Analysis**
- ▶ Incremental Analysis
- ▶ Other Techniques:
  - ▶ Future Worth Analysis
  - ▶ Benefit-Cost Ratio Analysis
  - ▶ Payback Period Analysis

## Rate of Return Analysis

---

- ▶ Internal Rate of Return
- ▶ Calculating Rate of Return
- ▶ Rate of Return Analysis
- ▶ Incremental Cash Flow Analysis

## Internal Rate of Return (IRR) Lender's Viewpoint

---

Year	Cash flow	
0	-5000	1. We know that the PW of five payments of \$1,252 are equivalent to \$5,000 when interest rate is 8%.
1	+1252	
2	+1252	2. At the end of 5 years, the payments exactly repaid the \$5,000 debt with interest rate 8%. <i>We say the lender received 8% rate of return.</i>
3	+1252	
4	+1252	
5	+1252	

- ▶ The **interest rate** on the balance of a loan such that the unpaid loan balance equals zero when the final payment is made

## Internal Rate of Return (IRR)

---

- ▶ Simple Definition:
- ▶ Given a cash flow stream, rate of return (a.k.a. IRR) is the interest rate  $i^*$  at which the benefits are equivalent to the costs:
  - ▶  $NPW=0$
  - ▶  $PW \text{ of benefits} - PW \text{ of costs} = 0$
  - ▶  $PW \text{ of benefits} = PW \text{ of costs}$
  - ▶  $PW \text{ of benefits} / PW \text{ of costs} = 1$
  - ▶  $EUAB - EUAC = 0$

## Internal Rate of Return (IRR)

---

- ▶ Suppose you have the following cash flow stream. You invest \$700, and then receive \$100, \$175, \$250, and \$325 at the end of years 1, 2, 3 and 4 respectively. What is the IRR for your investment?

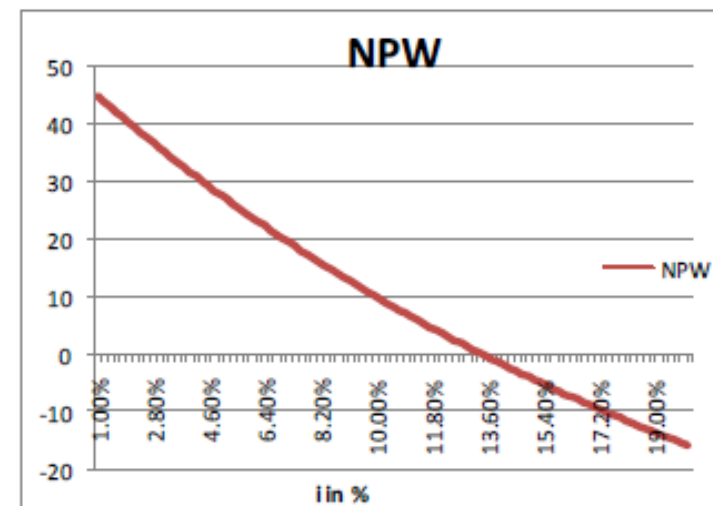

- ▶  $700 = 100/(1+i) + 175/(1+i)^2 + 250/(1+i)^3 + 325/(1+i)^4$
- ▶ Solving for  $i$  >>> *It turns out that  $i^* = 6.09\%$*

# Calculating Internal Rate of Return

- ▶ **Ways to find the IRR:**
- ▶ 1. Compound Interest Tables (you may need to use interpolation)
- ▶ 2. Trial-and-error
- ▶ 3. Numerically (Excel's IRR function, MATLAB, or other root finding methods)
- ▶ 4. Graphically
- ▶ If you have a CFS with an investment  $(-P)$  followed by benefits (non negative) from the investment:
- ▶ The graph of NPW versus  $i$  will have the same general form.
- ▶ It will decrease at a decreasing rate and have a value 0 at some unique value  $i^*$ .
- ▶ Where the graph has a value 0 defines the IRR.

$$NPW = -700 + 100/(1+i) + 175/(1+i)^2 + 250/(1+i)^3 + 325/(1+i)^4$$

# Example 1: Solution Using Interest Tables

---

▶ Given the following CFD, find  $i^*$

▶  $PWB/PWC = 1$

▶  $1252(P/A, i, 5)/5000 = 1$

▶  $(P/A, i, 5) = 5000/1252 = 3.993$

▶ From Compound Interest Tables:

$i=8\%$

Interest rate	(P/A, i, 5)
7%	4.100
8%	3.993
9%	3.890

## Example 2: Solution Using Interest Tables

---

- ▶ An investment resulted in the following cash flow. Compute the rate of return.

Year	Cash Flow
0	-\$700
1	+100
2	+175
3	+250
4	+325

$$\begin{aligned} \text{EUAB} - \text{EUAC} &= 0 \\ 100 + 75(A/G, i, 4) - 700(A/P, i, 4) &= 0 \end{aligned}$$

Solve the equation by trial and error

At  $i = 5\%$ ,

$$\text{EUAB} - \text{EUAC} = 208 - 197 = +11$$

At  $i = 8\%$ ,

$$\text{EUAB} - \text{EUAC} = 205 - 211 = -6$$

$i = 7\%$ :

$$\text{EUAB} - \text{EUAC} = 0$$

## Example 3: Graphical Solution

- ▶ Given the following CFS, find  $i^*$

Year	Cash
0	-100
1	20
2	30
3	20
4	40
5	40

- ▶ PW of costs = PW of benefits
- ▶  $100 = 20/(1+i) + 30/(1+i)^2 + 20/(1+i)^3 + 40/(1+i)^4 + 40/(1+i)^5$
- ▶  $NPW = -100 + 20/(1+i) + 30/(1+i)^2 + 20/(1+i)^3 + 40/(1+i)^4 + 40/(1+i)^5$

# Problem: 7-1

---

▶  $\$125 = \$10 (P/A, i\%, 6) + \$10 (P/G, i\%, 6)$

▶ **LHS=RHS**

at 12%, **RHS=**  $\$10 (4.111) + \$10 (8.930) = \$130.4$

at 15%, **RHS=**  $\$10 (3.784) + \$10 (7.937) = \$117.2$

▶  $i^* = 12\% + (3\%) ((130.4 - 125) / (130.4 - 117.2)) = 13.23\%$

## Problem 7-8

---

Year	Cash Flow	
0	-\$400	PWC=\$400
1	0	PWB = [\$200 (P/A, i%, 4) - \$50 (P/G, i%, 4)] (P/F, i%, 1)
2	+200	
3	+150	
4	+100	
5	+50	PWC=PWB

▶ **Try i = 7%**

▶ PWB = [\$200 (3.387) - \$50 (4.795)] (0.9346) = 409.03

▶ **Try i = 8%**

▶ PWB = [\$200 (3.312) - \$50 (4.650)] (0.9259) = \$398.08

▶  $i^* = 7\% + (1\%) [(\$409.03 - \$400) / (\$409.03 - \$398.04)]$

▶ = 7.82%

## Problem 7-10

---

Solve the following cash flow for the rate of return to within an  $\frac{1}{2}\%$ .

Year	Cash Flow
0	-\$500
1	-100
2	+300
3	+300
4	+400
5	+500

$$PWC = \$500 + \$100 (P/F, i\%, 1)$$

$$PWB = \$300 (P/A, i\%, 2) (P/F, i\%, 1) + \$400 (P/F, i\%, 4) + \$500 (P/F, i\%, 5)$$

$$PWC - PWB = 0$$

## Problem 7-10

---

- ▶ **Try  $i = 30\%$**
- ▶  $PWC = \$500 + \$100 (0.7692) = \$576.92$
- ▶  $PWB = \$300 (1.361) (0.7692) + \$400 (0.6501) + \$500 (0.2693) = \$588.75$
- ▶  $PWC - PWB = 11.83$
- ▶ **Try  $i = 35\%$**
- ▶  $PWC = \$500 + \$100 (0.7407) = \$574.07$
- ▶  $PWB = \$300 (1.289) (0.7407) + \$400 (0.3011) + \$500 (0.2230) = \$518.37$
- ▶  $PWC - PWB = 55.70$
  
- ▶ Rate of Return,  $i^* = 30\% + (5\%) [11.83/55.70] = 31.06\%$
- ▶ Exact Answer: 30.81%

## Rate of Return (RoR) Analysis

---

- ▶ Example statements about a project:
  - ▶ The net present worth of the project is \$32,000
  - ▶ The equivalent uniform annual benefit is \$2,800
  - ▶ The project will produce a 23% rate of return
- ▶ The third statement is perhaps most widely understood.
- ▶ Rate of return analysis is probably the most frequently used analysis technique in industry.
- ▶ Its major advantage is that it provides a figure of merit that is readily understood.

## Rate of Return (RoR) Analysis

---

- ▶ Rate of return analysis has another advantage: With NPW or EUAB one must choose an interest rate for using in the calculations.
- ▶ This choice may possibly be difficult or controversial.
- ▶ With RoR analysis no (exterior) interest rate is introduced into the calculations.
- ▶ Instead, we compute a RoR from the CFS.
- ▶ Warning: Relying only on RoR is not always a good idea.

## Rate of Return (RoR) Analysis

---

- ▶ **Example:** Which of the following two investment options would you select?
- ▶ Option 1:
- ▶ Invest \$2,000 today. At the end of years 1, 2, and 3 get \$100, \$100, and \$500 profit; at the end of year 4, you get \$2,200.
- ▶ Option 2:
- ▶ Invest \$2,000 today. At the end of years 1, 2, and 3 get \$100, \$100, and \$100 profit; at the end of year 4, you get \$2,000.

## Rate of Return (RoR) Analysis

---

- ▶ Find out the implicit interest rate you would be receiving; that is, solve for the interest rate in which the PW of benefits are equal to your payments \$2,000.

- ▶ Option 1:

- ▶  $2000 = 100/(1+i)^1 + 100/(1+i)^2 + 500/(1+i)^3 + 2200/(1+i)^4$

- ▶ IRR:  $i = 10.78\%$

- ▶ Option 2:

- ▶  $2000 = 100/(1+i)^1 + 100/(1+i)^2 + 100/(1+i)^3 + 2000/(1+i)^4$

- ▶ IRR:  $i = 3.82\%$

Which deal would you prefer?

## The Minimum Attractive Rate of Return (MARR)

---

- ▶ The MARR is a minimum return the company will accept on the money it invests
- ▶ The MARR is usually calculated by financial analysts in the company and provided to those who evaluate projects
- ▶ It is the same as the interest rate used for Present Worth and Annual Worth analysis.

## Incremental Cash Flow Analysis ( $\Delta$ CFS)

---

- ▶ Suppose you must choose between projects A or B.
- ▶ We can rewrite the CFS for B as  $B = A + (B - A)$ .
- ▶ In this representation B has two CFS components:
  - ▶ 1. the same CFS as A, and
  - ▶ 2. the incremental component  $(B - A)$ .
- ▶ B is preferred to A when the IRR on the difference  $(B - A)$  exceeds the MARR.
- ▶ Thus, to choose one between B and A, IRR analysis is done by computing the IRR on the incremental investment  $(B - A)$  between the projects.

## Incremental Cash Flow Analysis ( $\Delta$ CFS)

---

- ▶ Steps to conduct  $\Delta$ CFS on two CFS's:
  - ▶ 1. Number them CFS1 and CFS2, with CFS1 having the largest initial (year 0) cost (in absolute value)
  - ▶ 2. Compute  $\Delta$ CFS = CFS1 - CFS2 (It's year 0 entry must be negative)
  - ▶ 3. Find the IRR for  $\Delta$ CFS, say  $\Delta$ IRR
  - ▶ 4. If  $\Delta$ IRR  $\geq$  MARR, choose CFS1; if not, choose CFS2
  
- ▶ Example: There are two cash flows: (-20,28) and (-10,15) and MARR = 6%.
  - ▶ 1. CFS1 = (-20,28), CFS2 = (-10,15)
  - ▶ 2.  $\Delta$ CFS = CFS1 - CFS2 = (-10,13)
  - ▶ 3.  $\Delta$ IRR = 30%.
  - ▶ 4.  $\Delta$ IRR > MARR  $\Rightarrow$  we choose CFS1 = (-20,28)

## Incremental Cash Flow Analysis ( $\Delta$ CFS)

---

- ▶ In summary, we compute the CFS for the difference between the projects by subtracting the cash flow for the lower investment-cost project (A) from that of the higher investment-cost project (B).
- ▶ Then, the decision rule is as follows:
  - ▶ IF  $\Delta IRR_{B-A} > MARR$ , select B
  - ▶ IF  $\Delta IRR_{B-A} = MARR$ , select either A or B
  - ▶ IF  $\Delta IRR_{B-A} < MARR$ , select A
  - ▶ Here, B-A is an investment increment.

## Why We Use $\Delta$ IRR in IRR analysis?

---

Years	A	B	B-A	
0	-10	-20	-10	MARR=6%
1	15	28	13	
<hr/>				
IRR	50%	40%		Select A
<hr/>				
$\Delta$ IRR <sub>B-A</sub>			30%	MARR < $\Delta$ IRR <sub>B-A</sub> Select B
<hr/>				
NPV	3.92	6.05		Select B
<hr/>				

- ▶ Although the rate of return of A is higher than B, B got \$8 return from the \$20 investment and A only got \$5 return from \$10 investment.
- ▶ Project B: you put \$20 in project B to get a return \$8.
- ▶ Project A: you put \$10 in project A (and \$10 in your pocket) to get a return \$5.
- ▶ From this example, we know that we can't evaluate two projects by comparing the IRRs of the projects. Instead, we use  $\Delta$ IRR and MARR to make the decision.

## Problem 7-47

---

Two alternatives are as follows:

Year	<i>A</i>	<i>B</i>
0	-\$2000	-\$2800
1	+800	+1100
2	+800	+1100
3	+800	+1100

If 5% is considered the minimum attractive rate of return, which alternative should be selected?

## Problem 7-47

---

Year	A	B	(B - A)
0	-\$2,000	-\$2,800	-\$800
1- 3	+\$800	+\$1,100	+\$300
Computed ROR	9.7%	8.7%	6.1%

The rate of return on the increment (B - A) exceeds the Minimum Attractive Rate of Return (MARR), therefore the higher cost alternative B should be selected.

## Problem 7-51

---

Consider two mutually exclusive alternatives:

Year	X	Y
0	-\$5000	-\$5000
1	-3000	+2000
2	+4000	+2000
3	+4000	+2000
4	+4000	+2000

If the MARR is 8%, which alternative should be selected?

## Problem 7-51

---

Year	X	Y	X- Y
0	-\$5,000	-\$5,000	\$0
1	-\$3,000	+\$2,000	-\$5,000
2	+\$4,000	+\$2,000	+\$2,000
3	+\$4,000	+\$2,000	+\$2,000
4	+\$4,000	+\$2,000	+\$2,000
Computed ROR	16.9%	21.9%	9.7%

Since X- Y difference between alternatives is desirable, select Alternative X.

## Summary

---

- ▶ RoR analysis is often used but not always well understood by practitioners
- ▶ RoR can be computationally difficult manually; a spreadsheet model helps reduce solution time
- ▶ If an exact RoR is not necessary, use the PW or AW methods
- ▶ Use incremental analysis when using IRR
