Abstract—The study aimed to investigate the constraints of incorporating online collaborative learning in tertiary ICT education in a Malaysian classroom and students' suggestions for improvement that may help in enhancing learning in ICT education. Data collected from interviews with students are analyzed using constant comparative method at two levels: within-case analysis and cross-case analysis, in order to generate meaningful qualitative themes. The findings indicated two keys constraints: technology-related contradictions, which are related to desire for synchronous feedback in forum discussions, cut and paste and plagiarism of ideas, and other technological distractions; and group discussion contradictions. These refer to repetitive and mixed-up postings, clashes on topics of discussion, and discussions being too formal. Suggestions for improvement are reported by students regarding aspects of personalizing an online collaborative learning template; and providing additional support for collaborating online.

Keywords-E-learning; Online collaborative learning; ICT education; Activity Theory

I. INTRODUCTION

While, previous studies have reported that online learning can be used as a tool to enhance and improve students’ learning, but its effectiveness depends on how the tool is utilized [3], [18]. Other studies have asserted that online learning can be used effectively if it is implemented within a model of student-centered learning in which learning through collaboration is encouraged, instead of the typical teacher-centered model [1], [11], [10], [12]. While a number of researchers have cited the benefits of incorporating collaborative learning in face-to-face environments [6], [15] there is little research on the benefits of incorporating online collaborative learning, especially in a teacher education context [1] in Malaysian Higher Education Institutions [2], [7], although there are research on online collaborative learning in the Malaysian context.

One of the advantages of online collaborative learning that has been the focus of much of this research is the potential to be an alternative solution to the shortcomings of individualized instructions. Johnson and Johnson [15] state that learning collaboratively in a group can result in higher achievements and knowledge retention than in competitive and individualistic learning. Furthermore, students involved in individualistic learning tend to depress achievement due to competitive and individualistic natures that isolate individuals from each other [15]. Johnson and Johnson [15] summarized some of the shortcomings of individualized instruction: (1) isolating students – working alone for long periods may lower personal motivation by increasing boredom, frustration, anxiety, and the perception that learning is impersonal; (2) limiting the resources and technology available to students, and the support and encouragement of peers; and (3) no cognitive benefits associated with explaining to peers and developing shared mental models (p. 786).

II. PROBLEM STATEMENT

The integration of collaborative methods in an online environment is not an easy task. There are several drawbacks to online collaborative methods in learning such as the “Free-rider effect” whereby a team member takes advantage of leaving the others group member to accomplish the task, “Sucker effect” whereby a capable member of a team realized that she or he is taken for a free-ride by others group member, “Status sensitivity” whereby a capable member dominating the task or activity, and “Ganging up on the task” whereby members of the group just working on the task to get it over as effortlessly and as swiftly as possible [6]. As such, learners are also reluctant to work together in online groups and they are often dissatisfied with their collaborative work [6]. These circumstances tell us that learners “struggle with the development of a sense of interdependence and inter-subjectivity within their online groups, but end up holding fast to subjective, individualistic conceptions of learning” ([6], p. 134). Such aspects could become more aggravated in online environments [6], due to inequity of “emotional dynamics, which are often cited as being critical elements of the collaborative learning process” ([1], p.68).

Despite the above shortcomings, collaborative learning is widely reported positively in online learning literature and in fact is widely acknowledged as an effective instructional method in both traditional and distance learning environments research [16], [27]. With the limited number of studies on pre-service undergraduate teacher students in online collaborative learning environments [1], [11] and specifically in the Malaysian tertiary context [2], [7], [23], this study therefore aimed to investigate the constraints of incorporating online collaborative learning in tertiary ICT education in a Malaysian classroom and suggestions that may help for further improvement of practice.
III. THE PURPOSE OF THE STUDY

The purpose of the study was to identify potential constraints or issues of online collaborative learning when it was used for teaching and learning through the university’s Course Management System (Moodle) in tertiary Malaysian ICT education classroom. In addition, this study also aimed to propose some suggestions to address the particular constraints and issues. This study intended to answer the following research questions:

- What are the perceived constraints of online collaborative learning? and
- What are students’ suggestions or recommendations for improvement of online collaborative learning in tertiary ICT education?

IV. METHODS

The research in this study employed qualitative methods, namely semi-structured group interviews with students and analyzed using constant comparative method at two levels: within-case analysis and cross-case analysis, in order to generate meaningful qualitative themes [13], [19].

V. PARTICIPANT

The students participating in the research were Malaysian undergraduate pre-service teachers from three different programmes of Science and Mathematics, with specialization in Computer Education, namely, Science and Computer with Education (Chemistry) (SPK), Science and Computer with Education (Physics) (SPP), and Science and Computer with Education (Mathematics) (SPT). The students in each programme were in the second year of their study and were enrolled in a Computer Education course known as Authoring Language, which was conducted under the Department of Educational Multimedia, Faculty of Education at the Universiti Teknologi Malaysia. The teaching and learning in the Authoring Language course consisted of conventional face-to-face teaching lectures together with online participation through the university’s virtual Learning Management System (Moodle). The course ran for 15 weeks, comprised of 13 weeks of lectures, and one week each of mid-semester break and study week. During the course, students in each programme were formed into groups of 4-6 with a total of nine groups involved. The collaborative group task(s) were designed to enable groups in each programme to participate online and be involved in the creation of a solution to a problem case study. The designed collaborative group task(s) are explained as follows:

- Task 1 which required students to discuss the concept of Authoring Language with the goal of fostering students’ participation through sharing information, negotiating and making decisions as a group in order to improve their understanding and knowledge to select an appropriate authoring tool, as well as preparing the group for Task 2.
- Task 2 was specifically designed to foster collaboration and to build upon knowledge from the previous weekly activities in Task 1 as well as preparing the students for their final individual course assignment.

- Task involved the process of re-designing an existing Authoring Tool into a new and dynamic design which required an online group discussion of this new design before development went ahead.

VI. ANALYTICAL FRAMEWORK

The analytical framework for analyzing constraints and suggestions for online collaborative learning was provided by Activity Theory [8]. Activity Theory is progressively being used within the area of research such as humanities and computer interaction [16], [21], in research into distributed learning [24], for conceptualizing online community in educational setting [3] and for designing constructivist e-learning environment [14], [25].

Within an activity system illustrated in Fig. 1, students are portrayed as subjects interacting with objects to attain desired outcomes. The object of activity system is the goal (or motive) and the interaction is mediated through the use of tools (or technology affordances for students in the activity). Similarly, the relationship between subject and community is mediated through rules. Rules are described as any formal or informal regulations (or pedagogical rules) which have an effect on activity are designed. The affiliation between community and object is mediated through division of labor, which refers to how the tasks are socially distributed between the students. Previous researchers indicate that an online learning environment can be represented as an activity system that involves the aspects of technology, pedagogy and social [3], [26].

![Figure 1. The component of an activity system [8].](image-url)

Activity system is also embedded with internal contradictions [8]. These contradictions are referred as tensions or conflicts as result of interaction by the components of the activity system. For example, Barab et al. [4] described that contradictions as outcome of “exchange value of what is learned” and as outcome of “use value of learning because of its importance in addressing real-world problems” (p. 80). Tensions are crucial in developing the understanding of what motivates particular actions of activity system and its evolution. Although, tensions can also be associated of as system dualities through the
interplay of its components but can help support the continued innovation of the system [4]. Wenger [28] described that the interplay of system dualities within activity system can be used to leverage they dynamics aspects of the system without treating them as incompatible components where one part or the other can be purged or removed. The changes to activity system are driven by tensions of the systems as well as to develop [4].

Activity theorists see contradictions as sources of development [3], [8], [14]. Engeström [8] characterizes a contradiction as “a social, societally essential dilemma which cannot be resolved through separate individual actions alone – but in which joint cooperative actions can push a historically new form of activity into emergence” (p. 16). The resolution of contradictions, according to Engeström [9], takes place in the process of “living movement leading away from the old” (p. 16), when a goal or object of the system transformed into an outcome. For instance, the everyday decision making situation in which a person in conflicting with his/her decision may be influenced by immediate circumstances that influence his/her final decision-making. This is consistent with the notion of knowledge construction within a learning community where knowledge is constructed as results of interaction and negotiation of conflicting and different understanding [25]. Fig. 2 depicts contradictions in an activity system model.

![Figure 2. Contradictions in an activity system model](image)

Based on the contradictions model of an activity system in Fig. 2, the analytical framework for identifying constraints of incorporation of online collaborative learning is developed as in Table 1.

VII. DATA ANALYSIS

Qualitative analysis was conducted on the data collected from interviews with. The verified interview transcripts by participants were analyzed using the constant comparative method at two levels: within-case analysis and cross-case analysis, in order to generate meaningful qualitative themes [13], [17], [19]. In this method, each individual group transcript was studied and emerging themes from the data were coded and compiled for each group. The emerging themes were then compared across groups and subsequently categorized into similar units of meaning. The categories were continually refined, changed, merged or removed and grouped accordingly. Cross-case analysis within and between groups was undertaken to explore relationships and patterns that emerged from the interactions within each individual group case.

In this study, main categories (e.g. Tools affordances and constraints, pedagogical rules and shared roles and responsibilities) were framed using Activity Theory which similar to the work of previous researchers [20], [21] that used pre-specified Activity Theory codes that addressed specific components in an activity system. All coding processes were conducted using NVivo 7.0, qualitative analysis software that facilitated data analysis by coding students’ quotes into a node, a term used by NVivo to denote category. All of the data in a node, e.g. eLearning environment, constraining and enabling factors, online group work, and roles and responsibilities, can be later viewed and reviewed in a single window, making it convenient and efficient for the researcher to conduct qualitative analysis on a large amount of data.

VIII. FINDINGS

The research findings are presented below, grouped according to the research questions.

**RQ 1: What are the perceived constraints of online collaborative learning?**

Two keys constraints and tensions of activities in the course were addressed and shared by students in the interviews. They are summarized and grouped into (1) technology-related contradictions, which are related to Subject-Tools-Object (Tools) and Subject-Rules-Object (Rules) as desire for synchronous feedback in forum discussions, cut and paste and plagiarism of ideas, and other technological distractions, followed by (2) group discussion contradictions which are related to Subject-Division of Labor-Object (Division of Labor). These refer to repetitive
and mixed-up postings, clashes on topics of discussion, and discussions being too formal.

A. Technology-related contradictions

Desire for synchronous responses in forum discussions

Some students felt that the delay feature of forum discussions did not fulfill their desire for immediate synchronous responses. This tension is revealed through Adam from Group 3, who said:

The best way for discussion is through chatting where we can get immediate response. Sometimes, when we ask a question in a forum discussion, there is no one person who wants to reply to the post. Even if we wait for a long time there is still no response to our question. The best example of chatting for forum discussion is through Yahoo Messenger [synchronous]. (Adam, Group 3, Int.)

Susan from Group 1 added that a consequence of not having an immediate response is that students tended to forget the message and this contradicts the reflective nature of a forum discussion:

The discussion is best when someone responds to your question immediately, or else they will forget what they want to tell you. (Susan, Group 1, Int.)

Based on this tension, several students from all nine groups expressed their preference for face-to-face discussion over forum discussion to compensate for its constraint. Wendy from Group 4 reported:

For me, we can get an immediate response during a face-to-face discussion, but if we discuss it in the eLearning, we only can get the response from our course mates when they log-in. We have to wait for some time and wait for other peoples’ responses. (Wendy, Group 4, Int.)

Cut and paste and plagiarism of ideas

Another technology-related issue stressed by students was the direct cut and paste feature. This was reported by John from Group 1 as irritating as the structure of the posting was difficult to follow and understand. He said:

In my opinion, not all of us can present their ideas through words and writing. Sometimes we present better in words, but for discussion in eLearning, people who give out their ideas might copy their post from the Internet. In this situation, the idea is that their contribution is not originally from them and sometimes we do not understand the content. (John, Group 1, Int.)

Because of the ease of cutting and pasting messages in a forum discussion, some students felt that this could lead to plagiarism of ideas. Dennis from Group 7 pointed out:

There are possibilities of the ideas that have been pointed out by other people. Ideas that have been mentioned in discussion should not be pointed out again. People might say we copy someone’s idea. (Dennis, Group 7, Int.)

Other technological distractions

The multi-tasking feature of a computer operating system that allows the user to run multiple applications is another tension that students addressed. Hamesh from Group 9 stressed:

There’s always a problem during online that we do not focus only at one web page. Even if we log in to eLearning, while waiting for eLearning website page to be loaded, we are prone to visit other website pages like Facebook, YouTube and similar. (Hamesh, Group 9, Int.)

Some students viewed this tension as hindering their participation in the eLearning forum, as Aaron from Group 4 reported:

Like my own experience participating in the forum, while waiting to be logged-in which took some time, I like to open other websites which actually ended up by spending my time on that website instead of eLearning forum [laughed]. (Aaron, Group 4, Int.)

B. Group discussion contradictions

Repetitive and mixed-up postings

Because of the task goals of inter-group discussion to foster online inter-group collaboration across different programmes of studies (Chemistry, Physics and Mathematics Education), some students felt it was frustrating when some groups repetitively mixed-up their postings when completing the task. William from Group 1 said:

For example, discussions with SPT [Mathematics] group, where ideas that have been discussed were mixed-up. The worst part is where they kept discussing the same things over and over. (William, Group 1, Int.)

Lincoln from Group 8 added her frustration when some students posted repetitive, unrelated mixed-posts which contradict task goals:
In addition, when someone replies to the discussion in the forum and suddenly there is someone who replies to the post but it is not really related to the topic, such things will continuously happen to the next replies. (Lincoln, Group 8, Int.)

**Clash on topic of discussion**

Some Physics students felt some tensions and constraints in finding a suitable shared discussion topic that could accommodate different interests of programmes of studies, especially with Mathematics students, which contradicts task goals. Sandy from Physics Group 4 reported:

SPT [Mathematics] students discuss software that relates with Mathematics that can be used in their teaching, while we discuss software that relates with Physics and it depends on the suitability of the software to accommodate the Maths and Physics subject. (Sandy, Group 4, Int.)

Meanwhile, Elizabeth from Chemistry Group 1 found this tension occurred when Physics and Mathematics students focused on their related areas and expertise, but not inter-related areas and expertise, which contradicts task goals. Elizabeth from Chemistry Group 1 reported:

Like I said just now, SPP [Physics] come out with different ideas that suit their subjects, while SPT [Mathematics] come with their subjects, which are not related to SPP [Physics]. (Elizabeth, Group 1, Int.)

**Discussion being too formal**

Because discussions were evaluated as a part of the course assessment requirement, some students felt that it was in their interest to discuss it formally which is in line with the academic assessment requirement. However, some students faced dilemmas and tensions to accommodate the interplay between their non-academic identities and tertiary identities. Maggie from Mathematics Group 9 stressed:

We would not be able to point out what we want to say actually because we feel forced to do so. When we talk about fact, we feel that way rather than if we discuss it in the idle talk, where we feel free to talk about our feelings. We know that we will be evaluated based upon our opinions and thoughts that we share in a serious discussion. If it is a general topic, I will discuss it normally without feeling forced to do it, and sometimes if I feel I am being forced I tend to pretend to be another person while discussing. Even in writing, I will write it formally, the same as I did while discussing, if that is a fact thing and is going to be evaluated. (Maggie, Group 9, Int.)

**RQ 2: What are students’ suggestions or recommendations for improvement of online collaborative learning in tertiary ICT education?**

Suggestions and insights for further improvements were shared by nine participating groups through interviews and they are: personalizing an online collaborative learning template, and additional support for collaborating online.

A. **Personalizing online collaborative learning template**

Five groups from the interviews raised the importance of having personalized and attractive educational layout and communication as supplementary to the course. Adam from Physics Group 3 reported:

Attractive layout that students feel familiar with, like general forum with chat style in which students can directly communicate, like Peer-to-Peer (P2P) application which integrated in the forum with different layout style that students find attractive and familiar to them. (Adam, Group 3, Int.)

Two students from Group 5 and 8 suggested the use of structured postings and concept linkers so that it can help students to locate information if discussion postings were overloaded. The first point is exemplified by Marry from Mathematics Group 5 and the second point by Peter:

The discussion will be held according to the date that has been assigned by the group member. For example, I have to access on the second day so I need to know the ideas that the previous person has contributed. (Marry, Group 5, Int.)

If there are links to these concepts, it will help us to find the information and we can direct our information-seeking in the right direction. (Peter, Group 8, Int.)

B. **Additional supports for collaborating online**

All groups raised the importance of establishing additional support for collaborating online. This includes clear guidelines and ways of communicating online. Mike from Mathematics Group 8 stressed:

I think the students are not very familiar learning through the eLearning, though they have learnt the eLearning skills during their first year and also because of the attitude of the students towards the eLearning. I think we need to practice the eLearning culture by being active in using eLearning and support others to change bit by bit. (Mike, Group 8, Int.)
IX. CONCLUSION

The study has shown that the online collaborative learning activities are helpful in facilitating students’ learning but also have undesirable constraints such as technology-related contradictions (such as a desire for synchronous feedback in forum discussions, cutting and pasting and plagiarism of ideas, and other technological distractions) and group discussion contradictions (such as repetitive and mixed-up posts, clashes on topics of discussion, and discussions being too formal). However, constraints being inextricable aspects of online collaborative learning activities are consequently used as points of reference for further teaching and learning improvement.

ACKNOWLEDGMENT

The authors would like to thank the Universiti Teknologi Malaysia (UTM) and Ministry of Higher Education (MoHE) Malaysia for their support in making this project possible. This work was supported by the Fundamental Research Grant Scheme (Vote No.4F171) initiated by UTM and MoHE.
